1654. *The interior navigation of England* is justly regarded as one of the prime sources of her prosperity. Smith had long ago remarked, that, important as were the advantages of foreign commerce, they were not equal to that carried on by the different parts of a great country within itself; and that all the countries distinguished by wealth and civilisation had been remarkable for the extent of their inland means of conveyance, either bestowed by nature or formed by art. China, Holland, and Lombardy had afforded striking instances of canal navigation and its advantages; but in those countries, vast flat plains, of soft materials, and already traversed by numerous rivers, invited to this operation, which could be effected by mere mechanical section. The territory of England, on the contrary, is diversified by many rugged tracts; and its eastern and western rivers and their tributaries, which it was the main object to unite, were separated by a chain of considerable and somewhat rugged hills. Till the middle of last century, the making of canals did not enter into the system of English economy. In 1755 was formed the Sankey canal, a line of twelve miles, to supply Liverpool with coal from the pits at St. Helen's. The grand example then set by the Duke of Bridgewater gave a general impulse to the nation. Since that time, upwards of 30,000,000*l.* sterling have been expended in this object. Twenty-one canals have been carried across the central chain of hills, by processes in which no cost has been spared; all the resources of art and genius have been employed; and there has arisen a professional body of civil engineers, whose sole occupation is to plan these great public works, and contrive the means of their accomplishment. Every obstacle, however formidable, which nature could present, has been vanquished. By locks, and by inclined planes, the vessels are conveyed up and down the most rugged steepes; they are even carried across navigable rivers by bridges. When other means fail, the engineer has not hesitated to cut through the heart of rocks and hills a subterraneous passage. Of these tunnels, as they are called, there are said to be forty-eight, the entire length of which is at least forty miles.

1655. *The operations of the Duke of Bridgewater* gave the great impulse to the system of inland navigation. That nobleman formed the plan of opening a communication between Manchester and his extensive coal mines, at Worsley. The obstacles were so great, both from nature and art, that the attempt must have proved abortive, had he not been seconded by the genius of Brindley, who, from a common millwright, raised himself to be the first engineer of the age. Every resource of art was here called forth. The canal was carried through vast excavations, made partly in the interior of the mine itself; it was led by aqueducts over a succession of public roads, and over the river Irwell by a magnificent bridge, of that kind which left space for vessels with their sails spread to pass beneath. By deep cuttings, and by artificial mounds, in some places supported upon piles, a level of upwards of fifty miles was completed. The Duke expended, in this grand undertaking, his whole fortune, amounting to 350,000*l.*; and its failure would have left him destitute: but, as it immediately enabled him to reduce the price of coal in Manchester to one half, the trade in a short time yielded twenty per cent. upon his outlay, and rapidly produced an immense income. Brindley demonstrated on this occasion the superiority of canals over rivers, avoiding their circuitous line, their various obstructions, and their opposing currents, so that it became often eligible to lead a canal parallel to a river, and between the same points. So strongly did he urge this doctrine, that, in the House of Commons, when a member asked "for what purpose, then, nature had intended rivers?" he at once replied "To feed canals."

1656. *The Grand Trunk Canal*, an undertaking on a still greater scale, formed under the patronage of the Marquess of Stafford, by a course of ninety miles through Staffordshire, connects the Trent with the Mersey, Liverpool with Hull, and the eastern with the western coasts. It gave animation to the trade of all the districts through which it passed, particularly that of the Potteries, and served as a basis for various canals and railways branching from it. From a point near the commencement of the Grand Trunk, the Ellesmere canal has branched far into Wales, and conveys to Liverpool the mineral and agricultural produce of that principality. From its eastern termination, large branches have been extended to Derby, to Nottingham, to Grantham, and other considerable towns.

1657. *The Leeds and Liverpool Canal*, by a more northerly line of one hundred and twenty miles, connects the Mersey with the Aire, a tributary of the Ouse, and thus enables Liverpool and Hull to communicate by another line across the great cloth-manufacturing districts. An important branch of this canal is carried to Lancaster, and on to Kendal.

1658. *Meantime canals in the south* were no less actively prosecuted. From the vicinity of London the Grand Junction, at an expense of two millions, was carried by a line of ninety miles to the neighbourhood of Coventry. Near Daventry, the Grand Union strikes off, and joins the Grand Trunk, thus securing for London an inland communication with Liverpool, and with all the great manufacturing cities of the West. A great system of canals was formed round Birmingham, of which one result was to connect the Grand Trunk with the Severn, and thus to form a connection between all the four great rivers of England, and all its commercial and manufacturing cities. That from Birmingham to Wolverhampton has, within these few years, been remarkably improved by Mr. Telford. A canal had already been formed from Coventry to Oxford. That of the Thames and Severn joined these two main rivers at the highest navigable point of the former. The Gloucester and Berkeley is a lateral canal to the Severn, newly completed, by means of which Gloucester is connected with the Bristol Channel by a direct line, avoiding the sinuosity and obstructions of the river. The canals to the south of the Thames are not so important, nor is the commercial intercourse upon them so extensive. The principal are the Kennet and Avon canal, and the Berks and Wilts canal, through which a communication is formed from the Thames near Abingdon to the cities of Bath and Bristol. The total length of canals in Great Britain, excluding those under five miles, was 2581 miles.

1659. *Railways* form another contrivance, by which the conveyance of goods is wonderfully facilitated. By causing the wheels to roll over a smooth surface, first of wood, but now most commonly of iron, a single horse could draw a long file of loaded waggons, weighing from ten to twelve tons. The vehicles both for goods and passengers are now chiefly drawn by locomotive steam-engines. Railways were at first used only on a small scale, chiefly in the coal mines round Newcastle, for conveying the mineral from the interior to the surface, and thence to the place of shipping; and it is reckoned that round that city there is an extent of about three hundred miles of these railways. They were gradually employed on a greater scale, particularly in Wales, where the county of Glamorgan has one

twenty-five miles long, and in all two hundred miles of railway. But the most important work of this nature, and that most connected with the general interests of commerce, is the railway between Manchester and Liverpool, opened on the 15th September, 1830. It extends thirty-one miles, and is carried over sixty-three bridges, thirty of which pass over the turnpike road, and a spacious and handsome one over the river Irwell. The entire cost is about 820,000*l.*; but the intercourse has been so extensive as to promise an ample remuneration. The vehicles are drawn by locomotive steam-engines; those for the conveyance of passengers perform the journey in one hour and forty minutes. The Cromford and High Peak railway has also been a most useful work, being carried over the high mountainous district of Derbyshire, and connecting the two canals which bear these names. Its length is thirty-three miles, carried over fifty bridges, and rising to a level of 992 feet above the Cromford canal. The entire expense has not exceeded 180,000*l.* Other most extensive works of this nature are now projected, with a view to connect the leading points throughout the kingdom.

1660. On the Manchester and Liverpool railway the charge for conveyance of goods is limited by act of parliament; the charge for passengers is not limited. Great part of the profits arise from passengers, who go for curiosity from all parts of the kingdom. In the last half year (1833) the revenue amounted to 97,000*l.*, but the expenses were 56,000*l.*; leaving a profit of 41,000*l.*, on which a dividend of $4\frac{1}{2}$ per cent. was declared.

1661. *The common high roads* of the kingdom are also an object of high importance to trade and general intercourse. Half a century ago, most of them appear to have been in a miserable state. Mr. Young was then of opinion that for a great part of the year, the whole north of England should be considered as sea, and that a man should as soon think of driving into the German Ocean. He avers, "that in one of the most frequented roads of Lancashire, he had seen ruts four feet deep; and three carts overturned in the course of eighteen miles." The roads of England are now, perhaps, the best in the world, chiefly through the application of the turnpike system, under which they are made and repaired by tolls levied upon the travellers, and administered by county trustees. This system, which the populace at first blindly endeavoured to oppose, even by demolishing the turnpikes, has been found much more efficacious than that by which governments undertake to repair the roads from the public revenue, or by the exaction of personal service from the subjects. There are a few cases, however, where roads are to be carried through poor provinces, or form grand lines of national communication, in which government judges it expedient to assist, or even to undertake the entire construction of them. The principal instance in England was that of the high road from London to Holyhead, whence the packets sail for Dublin, a great part of which passed through the most barren and rugged districts of Wales. For the improvement of this road, parliament granted a large sum, by the judicious application of which, it has been rendered one of the finest in the world. In 1823, the turnpike roads extended in all to 24,531 miles in length. The amount of tolls was 1,214,000*l.*, burdened with a debt of 5,200,000*l.* There are 90,000 miles of by-roads, and others not turnpike, the maintenance of which by county rates and personal service costs about 1,500,000*l.* It would be unjust to withhold from Mr. Macadam due praise for that judicious method of structure by which the high-roads of England have been brought to a state of improvement in an eminent degree conducive to rapidity and safety of travelling, and to that frequency of communication which is invaluable in a commercial country. The praise of generally introducing that method of structure is undoubtedly his; and no competitor has hitherto appeared who can even *repair* a Macadamised road so effectually as Mr. Macadam himself.

1662. *Bridges*, in a country intersected by numerous and often broad rivers, necessarily attracted a great share of attention; and the ingenuity and wealth of England have been employed in making extensive improvements in this branch of architecture. The very situation of the metropolis, divided into two parts by a river a quarter of a mile broad, demanded that every resource for this purpose should be employed. From London Bridge, built in the twelfth century, with narrow and unequal arches placed upon huge masses, which left only a difficult and dangerous passage for the waters beneath, a successive improvement may be traced to the bridges of Westminster, Blackfriars, to that of Waterloo or the Strand, and finally to the new London Bridge, in which all the principles of construction seem to have been carried to the highest perfection. Southwark Bridge is the most complete of any yet formed of iron. This species of bridge has the advantage of being lighter, and of requiring much fewer arches, than those of stone. The first example in this country was that of Colebrook Dale, over the Severn; next, that of Sunderland, on a much greater scale, but each consisting of a single arch. That of Vauxhall far exceeded both, but has been itself much surpassed by Southwark bridge, in which height and strength have been united in a degree hitherto unexampled. A still more daring form has been given to this material by bridges of suspension, formed by iron chains stretched across, and supported by fixed points on each side. It is remarkable that this construction, on a certain scale, has existed in China from the earliest ages. The Americans were the first to adopt it of any modern nation. Captain Brown, in 1819 and 1820, constructed over the Tweed, near Kelso, a flying bridge, by which loaded wagons can pass in perfect security, and with only the feeling of a slight oscillation. The same able engineer afterwards constructed bridges of embarkation at Newhaven and at Brighton. But the greatest undertaking of this kind yet

executed is the Menai Bridge (*fig.* 138.), over the strait which separates Wales from Anglesey. After building arches of masonry on each side, Mr. Telford united them, though separated by the distance of five hundred and sixty feet, by a bridge of suspension, composed of iron chains. These bridges recommend themselves by their economy, and by their occasioning no interruption to the navigation of the rivers beneath.

MENAI BRIDGE.

SECT. VI. *Civil and Social State.*

1663. *The population of England* in former times was imperfectly known, being calculated only from very vague surveys and estimates. In 1377 the results of a poll-tax were given as 2,300,000; but from the many evasions to which such a census would give rise, that number was probably below the truth. In the reign of Elizabeth, during the alarm of a menaced Spanish invasion in 1575, a pretty careful survey was made, the result of which gave 4,500,000. At the time of the Revolution, the increase appeared to be about

a million. From the commencement of the present century decennial enumerations have been made, of which the following are the results: —

	Population, 1801.	Increase per cent.	Population, 1811.	Increase per cent.	Population, 1821.	Increase per cent.	Population, 1831.
England - - -	8,331,434	14½	9,551,888	17½	11,261,437	16	13,098,338
Wales - - -	541,546	13	611,788	17	717,438	12	805,236
Army, Navy, &c. -	470,598	- -	640,500	- -	319,300	- -	277,017
Total -	9,343,578	27½	10,804,176	34½	12,298,175	28	14,180,591

Proportion of deaths, marriages, &c. to the population. — Among the facts that attest the improved condition of the people of England since 1770, the extraordinary diminution in the rate of mortality is one of the least equivocal. In 1780, the deaths in England and Wales amounted to about 1 in 40 of the population. In 1790, the rate of mortality was reduced to about 1 in 45; in 1811, it was 1 in 52; and at an average of the five years ending with 1830, it was 1 in 54! The improvement has been particularly conspicuous in London, Manchester, and other great towns; and is, no doubt, to be ascribed to the more comfortable situation of all classes, the greater attention paid to cleanliness, &c. The proportion of marriages to the population has recently declined. In 1760, there was 1 marriage for every 116 individuals. In 1780, the proportion had declined to 1 in 118. During the five years ending with 1810, it was as 1 to 122; and during the five years ending with 1830, it was as 1 to 129. But this decrease is to be ascribed wholly to the greater prevalence of moral restraint, the proportion of illegitimate births not having increased. The number of births to a marriage in England is estimated at about 4. Consumption is the most fatal disease, and next to it are fevers, apoplexies, &c. The small-pox has been almost wholly exterminated; but the measles are said, we know not with what truth, to have latterly become more destructive than formerly.

1664. *The national character of the English* exhibits some very bold and marked features. Of these the most conspicuous is that love of liberty, which is both a cause and an effect of their free constitution, and which pervades all classes. The liberty for which the English have successfully contended, includes the right of thinking, saying, writing, and doing most things which opinion may dictate and inclination prompt. The knowledge that the highest offices and dignities in the state are accessible to all, redoubles their activity, and encourages them to perseverance. It is but little more than a century since they began to be distinguished as a manufacturing and commercial people, yet they have already outstripped every other nation in mechanical ingenuity, in industry, and in mercantile enterprise. The enormous increase of capital, and the substitution of machinery for human labour in most of their manufactures, seem likely at no distant period to produce a total change in the condition of British society. Much of its tone is given by the landed gentry; a numerous body, whose estates, though generally considerable, are not enormous: while, on the Continent, landed property is usually in one or other of two extremes; either divided into minute portions, or partitioned into a few princely domains. The English gentry, unlike their continental neighbours, reside during the greater part of the year at their country seats; appearing in London and at court only for a few months in the spring. In this class, and indeed among the English in general, an uncontrolled temper, elevated by the feeling of independence, often impels individuals into extremes both of good and evil. Nowhere exists a purer spirit of patriotism; nowhere break forth more violent excesses of faction. In no country of Europe, perhaps, are there so many men who act steadily upon principle; yet in none exists, at the same time, so large a proportion of individuals living in habitual and open violation of all principle, and frequently in contempt of legal ordinances. Amidst numerous examples of judicious economy, we find some instances of sordid avarice; and too many of inconsiderate and boundless extravagance. Domestic life is cultivated by the English more sedulously than by any of the continental nations; the sanctity of marriage is more carefully guarded; and chastity in the female sex more strictly observed. The French, before the revolution, accused the English as deficient in the minor courtesies, — as blunt, rude, and untutored in the arts which render society agreeable; but they themselves have lost, in consequence of that revolution, much of the refinement on which they formerly prided themselves. In its minor features, the English character has undergone various changes. The vices of drinking and swearing, once so prevalent among country squires, among officers of the army and navy, as well as in what is called the gay world, are happily no longer fashionable; even the labouring classes, imitating the example of their betters, begin to be ashamed of them. Horse-racing, hunting, and rural sports, are carried to excess by some of the country gentlemen; and the more barbarous practice of boxing still has its zealous cultivators. Perhaps the most estimable quality of the English is their love of justice; the source of all honourable dealing among the higher classes, and of what is emphatically called *fair play*, in the transactions of humbler life. The principle, that a man's word should be his bond, is acted upon most rigorously where the greatest interests are at stake; as on its observance more than on that of any law that has been or can be devised, the commercial and financial prosperity of the country depends. The English are the most provident people in the world. More than a million of individuals are members of friendly societies, and the deposits in savings banks exceed 13,000,000*l*. The great extension of life insurance affords another proof of this laudable disposition. The English also deserve to be called a humane people, zealous, both from feeling and from principle, for the promotion of every thing that tends to the welfare of their fellow-creatures. In that cause they have ever been foremost; and, indeed,

the character of a philanthropist, a man devoting his whole life to the service of his fellow-men, seems peculiar to this nation. — *Crime* in England has undergone a very considerable change. Highway robbery, so prevalent towards the beginning and middle of last century, is now nearly unknown, and all sorts of crimes of violence have been materially lessened. On the other hand, there has been a very rapid increase, particularly within the last sixteen or twenty years, of crimes against property. In point of fact, however, this increase has not been so great as it appears; for, owing to the establishment of a regular police, and of police magistrates, in most considerable towns, a much larger number of offences are now detected, and made the subject of prosecution, than formerly. Latterly the abominable crime of arson has been carried to an extent unknown at any former period. It is of so destructive a nature, that it ought to be met by the most prompt and energetic measures. A good number of crimes have arisen out of combinations of workmen; and the extent to which these sort of unions are now carried, and the dangerous nature of the objects to which they may be, and, indeed, have been, perverted, render them the objects of much jealousy and suspicion. A material change has recently been effected in the criminal law of England, by the abolition of an immense number of capital punishments. On the whole, we believe the change will be beneficial; though in some instances it has probably been carried too far.

1665. *Provision for the Poor.* A compulsory rate has been levied on all kinds of fixed property, for the support of all impotent, poor, and unemployed persons, ever since the reign of Elizabeth. In 1700, the rates amounted to about 1,000,000*l.*, and, notwithstanding the increase of population and of taxation in the interval, they were little more than 2,000,000*l.* at the close of the American war. In 1795 several ill-considered changes were made in the mode of granting relief, and the pernicious practice of eking out wages by contributions from the rates was then also adopted. From this period, down to the termination of the late French war, the progress of the rates was very rapid, so that they amounted to 9,320,000*l.* in the year 1817-18. They have since been reduced, but they still amounted in 1831-32 to 8,509,000*l.* Various and very discordant opinions have been entertained as to the policy of this provision. On the whole, however, we are inclined to think that it has been productive of a much greater amount of good than of evil. It has made the landlords and people of property oppose the unnecessary progress of population, the multiplication of cottages, and that subdivision of the land which has been the bane of Ireland; while it has maintained the public tranquillity by affording a refuge to the poor, and sustaining them in periods of distress and difficulty. The abuses arising out of the practice of paying wages out of rates are not inherent in the system. They were engrafted upon it so late as 1795, and may, and it is to be hoped will, be entirely removed. A reform of this sort would of itself take nearly a third part from the rates.

1666. *The English are, in general, a people soberly religious, though the nation, among its other excesses, has presented striking displays of infidelity and fanaticism.* The Church of England was established in the reign of Queen Elizabeth, when the reformation was completed which had been begun in that of Henry VIII. It is an integral part of the constitution, having for its head the king, who is declared to be, "in all causes ecclesiastical as well as civil, within these his dominions, supreme." By virtue of his authority, as head of the church, he nominates to vacant bishoprics and certain other preferments, constitutes or restrains ecclesiastical jurisdictions, inflicts ecclesiastical censures, and decides in the last resort in all ecclesiastical causes, an appeal lying ultimately to him in chancery, from the sentence of every ecclesiastical judge. In respect to its church government, England is primarily divided into two provinces or archbishoprics, Canterbury and York. Each province contains various dioceses or seats of suffragan bishops, Canterbury including twenty-one, and York three, besides the bishopric of Sodor and Man, which was annexed to it by Henry VIII. Every diocese is divided into archdeaconries, of which the whole number amounts to sixty, each archdeaconry into rural deaneries, which are the circuits of the archdeacon's and rural dean's jurisdiction; and each deanery into parishes, towns or villages, townships, and hamlets. The principal church of each see is appropriately called the *cathedral* church; it is possessed by a spiritual body corporate, called a dean and chapter, who are the council of the bishop, but derive their corporate capacity from the crown. Chapters are usually composed of canons and prebendaries; the maintenance or stipend of a canon as well as of a prebendary being a *prebend*. Prebendaries are distinguished into simple and dignitary. A simple prebendary has no cure, and nothing but his revenue for his support; a dignified prebendary has always a jurisdiction annexed, which is gained by prescription. The archdeacon has authority in the bishop's absence to hold visitations, and under the bishop to examine clerks previous to ordination, and also before institution and induction. He has also power to excommunicate, to impose penances, and to reform irregularities and abuses among the clergy, and has charge of the parish churches within the diocese. Below the archdeacon and the ecclesiastics composing the chapter, no member of the Church of England is entitled to the appellation of dignitary. The inferior orders constitute what is called the parochial clergy. The principal *person* of a parochial church is entitled either rector or vicar, that title, which is really more appropriate and honourable, having become corrupted by vulgar misuse. Curates are either temporary or perpetual; temporary when employed by the rector or vicar, and perpetual when appointed to officiate in parishes which have neither. The revenues of the church of England are very extensive; and considering the different offices and gradations of its members, very variously distributed. The rental subject to tithe has been stated, in returns made to parliament, at 20,000,000*l.* Besides the tenth of this amount, that is to say, the *tithe*, the clergy have other funds, which are supposed to raise their entire income to upwards of 3,000,000*l.* The episcopal revenues are of various amounts; that of the see of Durham is estimated at 30,000*l.* per annum, and is usually considered the largest. The lowest, that of Landaff, falls short of 3000*l.* The prebends enjoyed by canons and prebendaries are some of them very ample; those which exceed 1000*l.* a year are called golden prebends. Those dignitaries are also competent to hold livings as rectors and vicars. The salaries of curates were formerly in many cases extremely small; but, by a legislative provision and by funds allotted out of the public revenue, most of them have been augmented in proportion to the value of the benefice and its population: 80*l.* a year is the lowest stipend, and, if the living be worth 400*l.* per annum, the bishop may allow the curate of such living 100*l.* a year, whatever be its population.

1667. *The Church of England has produced many divines eminent for their piety and learning, whose writings on the general doctrines of revealed religion, and on the evidences of its divine origin, have commanded the respect and veneration of all Christendom, and have furnished arguments against infidelity, of which even the doctors of the Romish church frankly avail themselves.* Such examples are cited as proofs of the advantages arising from a richly endowed establishment. Its more learned votaries, holding academic or other offices, to which no laborious duties are attached, have been enabled to employ themselves in pursuits the most important that can occupy the human mind. Independently of higher

motives, they might fairly be encouraged by the certainty that great attainments constitute a claim to preferment which is never disregarded when occasions present themselves. The highest dignities in the church are accessible to its humblest members.

1668. *In her intellectual character*, England may be justly considered as standing proudly eminent. Bacon, Boyle, Locke, Newton, Davy, with a long train of coadjutors, have disclosed to mankind perhaps a greater sum of important truths than the philosophers of any other country. Strong, clear, sound sense appears to be the quality peculiarly English; and her reasoners were the first to explode those scholastic subtleties which, having usurped the name of philosophy, so long reigned in the schools. It was their merit to discover and establish true philosophy, and apply it to objects of real interest and utility; and that merit is the greater, since the patronage bestowed on science has always been scanty, and the most illustrious of its cultivators have had to endure, and even to calculate upon, the indifference of the public. Their energies seem to have been roused, rather by the general stir and movement which was taking place around them among a great and free people, than by the prospect of any high personal rewards for their exertions.

1669. *In works of imagination*, the genius of the English is bold, original, and vigorous. In the drama, Shakspeare stands unrivalled among ancient and modern poets, by his profound and extensive knowledge of mankind, his boundless range of observation throughout all nature, his exquisite play of fancy, and his irresistible power in every province of thought and feeling, the sublime and the pathetic, the terrible and the humorous. England has to boast of other dramatic poets, whose works entitle them to eminence, although tinged by that dissolute tone of manners which followed the overthrow of puritanic austerity on the restoration of the monarchy. In epic poetry, Milton is acknowledged by common consent to stand first among the moderns. Spenser and Dryden are alike eminent, the one for sweetness, the other for versatility; while in correctness of taste, and the polished harmony of numbers, Pope has no rival among the poets of any modern nation. The style of English poetry which prevailed in the age of Elizabeth, and which was principally distinguished by a bold irregularity, has in modern times been revived. The works of Byron, Campbell, Scott, Moore, and Southey amply sustain the ancient poetical renown of England, in an age when originality seems to have been stifled by criticism throughout the rest of Europe.

1670. *In historical writing*, England has many illustrious names, among which that of Gibbon, notwithstanding all his faults, deserves an honourable place. In oratory, some of her statesmen have acquired great renown, though the general taste both in the senate and at the bar seems to delight rather in plain sense and in cogency of argument, than in those elaborate, ornate, and declamatory flights by which the great speakers of antiquity acted on the imagination and passions of their hearers.

1671. *The institutions for public education* in England are extensive and splendidly endowed. The two universities of Oxford and Cambridge are not only the wealthiest but the most ancient in Europe. They enjoy among other privileges that of returning each two members to parliament, and of holding courts for the decision of causes in which members of their own body are interested. They were certainly of ecclesiastic origin; and, in common with every university in Europe, conferred degrees in all the faculties, by authority derived from a papal bull; but they have long been considered as lay corporations. Their possessions and resources have been augmented by the munificence of successive sovereigns, as well as by the grateful bequests of opulent individuals. The establishments composing them are distinguished into colleges and halls; the latter being academical houses not incorporated or endowed, though they have had considerable benefactions, which are dispensed to the students in exhibitions limited to a stated period. Oxford has nineteen colleges and five halls; Cambridge has thirteen colleges and four halls, which last, however, possess the same privileges as the former. Each university is under the government of a chancellor, high steward, vice-chancellor, and other officers; the persons who preside over the different establishments as masters, wardens, rectors, principals, or provosts, bear the general denomination of heads of colleges. Their appointments are on a liberal scale, and each college has a number of fellowships to which large emoluments and easy duties are attached. They possess also extensive patronage in church livings to which their own members may naturally aspire, and a number of exhibitions or scholarships bestowed, some through favour, and others as the rewards of successful competition. These, though of considerable value, are not supposed adequate to defray the expense of a residence at an university, which, at the lowest, is calculated to amount to 150*l.* a year. On the books of each university are the names of many members who have long ceased to reside; but, exclusive of these, the number actually resident at Oxford may be stated at 3000, and those at Cambridge amount to considerably more. Students, according to their proficiency in learning, are entitled to the degrees of bachelor and master of arts, bachelor and doctor in divinity, and bachelor and doctor in the faculties of physic and law. The time required by the statutes to be occupied in study before each student can be qualified for taking those degrees is three years for a bachelor, and about four years more for a master of arts; seven years after that, he may commence bachelor of divinity, and then five years more entitle him to take the

degree of doctor in divinity. In law, a student may commence bachelor after six years', and in physic after five years' standing. Only one year's attendance and the hearing of a single course of lectures are required as preparatory for entering into holy orders; a preparation much less arduous than that which is required in universities under presbyterian discipline; but the lowness of the inferior church livings, and the expense of residence, may render it difficult to exact more from the greater number of candidates for ordination. The qualifications for a bishop exact a longer attendance and higher attainments, as they include the degree of doctor in divinity.

1672. *Whether highly endowed institutions be the most useful and efficient*, is a question often raised. It is said, that a teacher who has no dependence on the contributions of his pupils is apt to sink into indolence; and that, in an age remarkable not only for the rapid advancement but for the extensive diffusion of knowledge, such great establishments are liable to be outstripped, their progress being retarded by their adherence to antiquated studies and systems. Such a charge has certainly been made against the English universities, whose forms of instruction are in many respects peculiar to themselves. They can scarcely be said to include public lectures, an essential branch of instruction in most other universities. A few, indeed, have lately been founded; and others are sometimes given voluntarily by active members; but they are rather incidental appendages than constituent parts of a regular system. The established mode of instruction is by private tutors, who teach classical literature and the mathematics, the latter branch of study being particularly cultivated at Cambridge. The public examinations are conducted with great diligence and impartiality, and excite high emulation. The numerous lucrative fellowships may sometimes tempt their possessors to indulge in luxurious ease; but to those who are seriously disposed to study they afford a learned and dignified leisure, with all facilities for research, to an extent hardly attainable in any other sphere. The professorships, also, and the various annual prizes, present many honourable incentives to excellence, admirably adapted to awaken the sluggish, to encourage the timid, to confirm the hesitating, and give a salutary tone to that sensibility which always accompanies true genius, and often impedes its progress.

1673. *Of the two recent establishments, the London University and King's College, London*, it would be premature to say more than to express a hope that, by a generous emulation, they may realise the intentions and wishes of their founders.

1674. *Of the public schools of England*, the most distinguished are those of Westminster, Eton, Winchester, and Harrow. Although originally founded as charity-schools, yet being now appropriated to the education of boys of the first families, the habits formed in them are very expensive. Greek and Latin are almost exclusively taught there by masters eminently qualified; and Englishmen of education generally excel in the knowledge of both languages. Notwithstanding some disorders incident to these schools, the general training established in them is supposed to be hardy, independent, republican, and well adapted for the future legislators of a free state. For boys of the middle rank, and those destined for commercial pursuits, there are numerous private academies, commonly well conducted, and some of them entitled to very high commendation.

1675. *Colleges for the particular study of law and equity* have long been established in the metropolis, under the names of inns of court and inns of chancery. The principal of these are the Middle and Inner Temple, Lincoln's Inn, and Gray's Inn. Before any person can be admitted to practise as an advocate, he must be regularly entered in, and be a member of, one of the inns of court for five years, and must have kept his commons in such inn, twelve terms. In favour of those who have taken a degree of master of arts or bachelor of laws at an English university, three years are allowed as sufficient to be a member of the inn, but the twelve terms must be duly kept. After complying with these conditions, and paying the regular fees, the student may be called to the bar without having been required to make any public demonstration of his proficiency or ability.

1676. *Of primary schools for the great body of the people*, there formerly existed a considerable number; but the deficiency of them, at present, is greatly to be deplored. The metropolis, indeed, contains several, of which the most considerable is Christ-church Hospital or the Blue-coat School, in which about 1100 children are maintained and educated. This institution, founded by Edward VI., has been enriched by various benefactions, until its income amounts to 44,625*l*. From the report of a late parliamentary commission, also, it appears that the number of charitable foundations in different parts of the country amounts to 3,898, yielding an income of 65,395*l*. Of these, however, many give also board and lodging, so that their advantages can extend to only a small number; others have been neglected, and left exposed to those abuses to which old establishments are generally liable. So greatly was the influence of these institutions on the great body of the lower orders diminished, that within the last 30 years the larger proportion of labouring people were unable to read. The evils arising from want of education among them have, at length, been strongly felt; and very great exertions have been made, chiefly by the benevolence of private individuals, to remedy the defect. The system of mutual instruction, introduced by Lancaster and Bell, afforded the means of bringing knowledge within the reach of all classes

at a moderate expense. The British and Foreign School Society, founded in 1808, on the plan of Lancaster, had, in 1816, an income of from 2000*l.* to 3000*l.* a year. They maintained only one school in the Borough Road, where 700 children were taught, at an expense of 380*l.* Their funds were chiefly expended in an establishment for rearing teachers, who, during their initiation, were furnished with board and lodging; and were then sent out, with authenticated recommendations, to different parts of the country. In connection with this society, 200 schools for boys and 79 for girls have been established. In 1811 was founded the National Society, on the plan of Dr. Bell, and under the patronage of the church of England. In the course of four years it received subscriptions to the amount of 24,000*l.*, and this sum was employed for the establishment of a number of schools, in which about 7000 children are now educated. It has also contributed to the formation of 122 schools in different parts of England. "Union Schools" have been established with the same laudable object. Notwithstanding all these efforts, there was still found, in 1816, a great deficiency in the means of education. From the East Union District, containing a population of 250,000, it was reported that 12,000 children could pay for their education, 17,000 were educated by charity, 30,000 were uneducated. Of the second class, two thirds were taught in Sunday Schools by voluntary teachers, and by a process necessarily tedious and imperfect, at the rate of five hours a day. Although the provincial great towns have received great accessions to the means of education, yet it is to be apprehended that they are not, on the whole, much better provided than the metropolis; and that in the remote districts and country places the deficiency is still very great.

1677. *Of the scientific institutions of England* the foremost is "the Royal Society of London for improving Natural Knowledge." In its infancy it owed much to the protection of Oliver Cromwell; and, having survived the Commonwealth, was incorporated by royal charter, in 1663. Under its illustrious president, Sir Isaac Newton, it soon rose to great splendour, being the medium through which his grand discoveries were first communicated to the world. Under subsequent presidents, Sir John Pringle, Sir Joseph Banks, and Sir Humphry Davy, it maintained, in several respects, its former reputation, though the objects of pursuit were somewhat varied, and though numerous other establishments withdrew from it much of the public attention. The Society still publish an annual volume, in two parts, under the name of *Philosophical Transactions*. In the career of mathematics and astronomy it was surpassed by the National Institute of France; and it appears to have lost the spirit of emulation by which it was formerly animated. Its officers are a president, two secretaries, and a council of twenty-one. New members are balloted for, on a recommendation of three, and are elected if there be a majority of two thirds in their favour. The Society of Antiquaries traces its origin to the reign of Queen Elizabeth, but was not incorporated until 1821. It has published some interesting papers, amidst a mass of miscellaneous matter, in a series of volumes entitled *Archæologia*. Several private societies have been formed for the cultivation of particular branches of knowledge, by the union of individuals distinguished for their attainments in or devotion to those branches. Such are the Linnæan, instituted about twenty years ago, which flourished under the auspices of Sir James Edward Smith; and the Geological Society, under the able direction of Dr. Macculloch. Besides these and other institutions in the metropolis, most of the great provincial towns, as Manchester, Bristol, Derby, Liverpool, and Newcastle, have formed literary and philosophical societies, which have had to boast many distinguished names, and have made some important contributions to science and literature in their Transactions.

1678. *Public libraries*, and those auxiliary repositories called museums, have long been regarded as objects of primary interest among the enlightened nations of Europe. England, after having for a long period been reproached for coldness and apathy on this subject, became sensible of its importance, and made great exertions to repair the deficiencies caused by her neglect. The principal collections appropriated to public use have owed their origin to the spirit and enterprise of private individuals. Thus, the Bodleian Library at Oxford was the bequest of Sir Thomas Bodley, and was enriched by successive donations: it owes to government no contribution, except that arising from the statute securing to it a copy of every new work published in the united kingdom. The British Museum derived its first treasures from the collections of Sir Robert Cotton and Sir Hans Sloane; but in providing additions to them, the national funds have been liberally employed. It has acquired, through purchase by parliament, the Harleian and Lansdowne MSS., the libraries of Major Edwards and Dr. Burney, and several valuable collections of coins and minerals. It has also been enriched by gifts from Dr. Birch, Mr. Cracherode, and many other gentlemen. But the most superb donation ever bestowed on this or any other library is that of the entire collection of George III., presented to the nation by his late majesty. With this accession, the library, which previously consisted of 125,000 volumes, has been augmented by one half, and may take its place, though not the first place, among the great national libraries of Europe. The Museum is also very rich in specimens of natural history, particularly of mineralogy.

1679. *Institutions* of an humbler but highly useful character have sprung from the ge-

neral desire of knowledge which marks the present age. Their object is to communicate knowledge to the commercial classes, as well as to persons who have not opportunities for a regular course of study; and the chief means employed for this purpose are a library, a reading-room, and courses of lectures. Of these establishments, the first in eminence is the Royal Institution, founded in 1800, which has now an excellent library, and at which annual lectures are given by distinguished men of science. The London Institution, founded five years afterwards, has of late been conducted with renovated spirit, and may at length answer the expectations and intentions of its founders. A similar establishment, called the Surrey Institution, was commenced about the same period, but failed for want of funds. All the great commercial cities and most of the manufacturing towns have now their public libraries; indeed, Liverpool may claim the merit of having given the example to the metropolis in the foundation of her Athenæum and Lyceum. She has also long enjoyed the advantage of a botanic garden, of which London is still destitute. The efforts of the Horticultural Society may in time supply this defect.

1680. *Of the Fine Arts, that of painting* was, during a long period, greatly neglected in England, to the astonishment of those who expected that a nation eminent in intellectual attainments would have favoured so congenial a pursuit. Portrait painting, indeed, always met with encouragement. Yet Vandyke, the leader in this branch of art, was a foreigner. It was only toward the close of the last century that Reynolds formed a style decidedly English, and of distinguished excellence. Thenceforward the patronage of his late majesty, inviting by its example the co-operation of private individuals, gave a decided impulse to the art, and the enterprising liberality of Alderman Boydell, in particular, called forth the dormant talents of native professors who had been deterred from emulating those of the foreign schools. In history, West, Stothard, Fuseli, and Northcote; in landscape, the unrivalled Wilson, and after him Turner, Collins, Callcott; in familiar life, Wilkie and Mulready; and in other departments, men of different degrees of genius; raised the British school to at least an equal rank with those of continental nations in modern times. The department of portrait painting, in particular, enjoys a large share of public favour, and is regaining the ascendancy over that of history, the taste for which seems to be on the decline.

1681. *The Royal Academy*, under the immediate patronage of the king, consists of forty artists, including the president, while a number of others are attached in expectancy as associates. There are four professors, viz. of painting, of architecture, of anatomy, and of perspective, who annually read public lectures on the subjects of their several departments. To the schools of this academy free admission is given to all students properly qualified for receiving instruction, and there is an annual exhibition of paintings, sculpture, and architectural designs, to which all artists may send their works for admission, if approved by the committee appointed to judge them. For the farther encouragement of native talent, the British Institution was founded in 1805; it has a gallery in Pall Mall, which is annually opened, during a fixed period, for the exhibition and sale of the works of British artists. Subsequent to this annual exhibition, an assemblage of works by ancient masters is usually formed, to which students have access, and which is exhibited to the public for a limited time.

1682. *Public collections of paintings* are of national advantage, as they afford the means of judging by comparison the merits of the ancient and modern schools. In England, at an early period, some splendid collections had been formed, particularly that of Charles I.; but when the nation came under the austere sway of men who "cared for none of these things," the pictures contained in it were dispersed, and the greater part of them conveyed abroad. The palaces, however, still retained seven of the twelve cartoons of Raphael, and some master-pieces of the Italian schools. At later periods, some private collections gained celebrity: that formed at Houghton by Sir Robert Walpole was the most valuable, but it was purchased at his death by the empress of Russia. It was not until the convulsions caused on the Continent by the French revolution that England gained an opportunity of accumulating treasures which she had at length learned to appreciate. Works of art, preserved from the wreck of princely fortunes, and consigned for sale to relieve the distresses of their possessors, became objects of eager competition among the noble and the opulent of this favoured country. The splendid collection formed by the regent duke of Orleans was imported entire, and the greater part of it now embellishes the gallery of the Marquess of Stafford. The nobles of Italy, also, on the devastation of that country, were obliged to strip their palaces of these valued ornaments, and to dispose of them at low rates to English speculators. From those sources were formed the Grosvenor, the Angerstein, and many other rich private collections: thus the treasures of art in England, according to Mr. Buchanan, were more than doubled. Still the nation looked on with indifference; and it was not until 1824, when, on the death of Mr. Angerstein, the valuable assemblage of pictures left by that gentleman was likely to be dispersed, that ministers proposed to parliament to purchase it, and make it the basis of a national gallery. The time was past when such an establishment on a much grander scale might have been at once formed at a comparatively small expense, and enriched with the choicest treasures of France, Italy, and Spain. The National Gallery, however, has received additions both by purchase and bequest, and may

gradually attain that magnitude which will accord with the wishes and greatness of the nation.

1683. *Sculpture* is another of the fine arts which England was tardy in promoting; but it has now attained to great eminence, though confined to what may be called the sculptured portrait, and to monumental and historic memorials.

1684. *Architecture* has been judiciously patronised by the successive sovereigns and the principal nobility of England; and many recent specimens, both in the Grecian and the Gothic style, reflect honour on the living professors of the art.

1685. *Engraving* necessarily followed as a subsidiary to the arts of painting, sculpture, and architecture. The first masters of this art in England who rose to high eminence were Woollett, Strange, and Vivares; with them, among later artists, may be ranked Sharpe, Bartolozzi, Schiavonetti, Landseer, Bromley, Finden, Burnet, and Scott, whose productions have gained for them a well-merited and lasting reputation. In scientific engraving, Wilson Lowry stood unrivalled; he may indeed be said to have carried this useful branch of the graphic art to perfection.

1686. *Music* was at all times admired rather than systematically cultivated in England. If not permitted to claim Handel as her own, she can boast few native compositions comparable with those of Italy and Germany; though Purcel and Matthew Lock may rank among the first masters. Her cathedral music is indeed admirable for sublimity and pathos; but her lighter productions, consisting chiefly of songs, ballads, and glees, are suited only to enliven the theatre or the convivial assembly. An impulse, however, was given to the cultivation of the art in its higher departments, by the institution of the Philharmonic Society in 1813. Native composers and performers of the first eminence have arisen in England, and her wealth has attracted the most distinguished professors from foreign countries. Exhibitions of musical skill on a comprehensive scale have not been confined to the metropolis; for in different provincial cities periodical festivals have been held, in which, at vast expense, the chief instrumental and vocal talent in the kingdom has been concentrated. By these means, and by others which fashionable refinement has devised, or which public charity has called to its aid, a taste for music has been very widely diffused.

1687. *The literature of England* is eminently prolific; and as the public taste for novelties especially in the lighter departments, is insatiable, the publishing and selling of books forms one of the principal branches of her productive industry. The number annually published may be calculated from data afforded by existing regulations relative to the supply of a copy of every new work to each of the national libraries. In 1817, the British Museum received eight folios, eighty quartos, seven hundred and sixty-one octavos, and two hundred and eighty-seven duodecimos. There being also a considerable number not entered at Stationers' Hall, or not delivered, the entire value could scarcely be less than 600*l.*; and allowing an average sale of seven hundred and fifty of each work, the produce would fall little short of half a million. The number of old books sold in each year might perhaps be valued at half that amount. The proverbial complaint of the poverty of authors may now be considered as in a great measure redressed; at least it may be observed, that a popular writer often obtains an amount of copyright sufficient to maintain him in comfort, if not in affluence. Periodical literature has a very extensive circulation. In the metropolis nearly sixty magazines and reviews are published, of which the monthly value has been estimated at 6000*l.* Another important characteristic of the national spirit may be remarked in the immense circulation of newspapers, notwithstanding a heavy stamp-duty, the policy of which is very questionable. There are in London eight daily morning papers, and five daily evening papers; seven papers published thrice a week; and upwards of forty weekly papers. Of the latter species of newspaper, every provincial city has two or three, and every town of consequence has one. These journals contain debates in parliament, public and domestic news, prices of funds, of grain and other commodities, anecdotes and miscellaneous notices of every kind: their chief profit arises from the advertisements. The total number of stamps issued for the London newspapers in 1832 was 21,432,882. The total produce of the duty in that year was 490,451*l.* 6*s.* 8*d.*

1688. *The favourite amusements* of the English are those which combine the advantages of air and exercise. The stage, though eminently rich in dramas, and supplied with actors of high talent, is not here, as on the Continent, the habitual resort of the people. In former times hunting was almost the sole business of life among the English squires; and though their tastes are now much varied, this original pastime, in all its forms, continues to be eagerly followed. By the nobility and gentry, horse-racing is supported with equal ardour, and no country rivals England in the high excellence to which she has brought the breed of animals employed in this diversion. The races of Doncaster, of York, and above all of Newmarket, are attended by the most distinguished persons in the country for rank and opulence; and other race-courses attract great multitudes of miscellaneous spectators. The deep stakes, however, and the practice of laying high bets on favourite horses, operate too strongly as an incentive to gambling. Among the common people boxing matches present a similar occasion of laying wagers; but their popularity has been on the decline since certain unexpected results excited doubts respecting the good faith of some combatants, and suspicions of the corruptibility of others. Bull-baiting, though a still more barbarous amusement, was put down only by statute; and a legislator of some note argued earnestly against its abolition. The amusements of those who constitute the fashionable world are nearly the same which prevail elsewhere among persons of that class. The French, in their criticisms on our national habits and manners, say that our social entertainments are formed less for the enjoyment of the guests than for the display of the wealth and importance of the host; that our balls are too crowded for dancing, our *conversaziones* for conversation, and even our dinner parties for eating in comfort. Of the national out-door

games, those of cricket and tennis deserve especial commendation, from their tendency to enliven the spirits and invigorate the frame.

1689. *In their habits and modes of ordinary life*, the English may be called a domestic people, especially when compared with the French. Their dress is not remarkable for any thing but its general neatness, aptitude, and propriety. In regard to food, their taste is perhaps too much inclined to that which is solid and substantial, though it should be mentioned to their credit, that, as they require no rich sauces to stimulate appetite, they eat more moderately, even of animal food, than the French and the Germans. Roast beef or other viands cooked in the plainest manner, accord with the unsophisticated taste of the English, and the repast is not slowly despatched, being, perhaps, an object of less consideration here, than it is with our continental neighbours. The English love to dine together in large companies on any public occasion which can afford a plausible pretext for such an entertainment. A great dinner, followed by a long train of toasts, forms the bond of union to all political parties, and to all patriotic, benevolent, and even religious associations. In the metropolis, various anniversaries are celebrated by persons who are natives of the same county, or who have been educated at the same public school, or at the same college in either university. It is not the most uncommon thing in the world for the stewards or committee of these meetings to dine together on some day previous to the dinner, for the purpose of ordering it, and again on some day after it, for that of discharging the bill. In common with other northern nations, the English retain a taste for fermented or distilled liquors, which, however, has been in a great measure corrected and subdued among the higher and middle classes. Beer and porter constitute the staple drink of the great body of the people; but malt spirit of a cheap and very pernicious kind is still consumed in too great quantities by the lowest of the lower orders, especially in the metropolis, where, to the reproach of the legislature, it is rapidly accelerating their degeneracy. Among the middle classes the wines of Spain, Portugal, and Madeira are in general use; but the cellars of the rich are stored with the choicest products of the French vineyards. Convivial excess, so long the reproach of the English among foreign nations, has become comparatively rare, and is wholly discountenanced in all refined and elegant society.

SECT. VII. *Local Geography.*

1690. *England and Wales* are divided into counties or shires. Wales, until the time of Edward I., was an independent principality, but is now an appendent territory, of very inferior magnitude. It has still, however, its own courts of judicature, and retains some national peculiarities.

1691. *The division of England into counties or shires* was originally made by Alfred. Each county is under the jurisdiction of a lord lieutenant, a sheriff, and justices of the peace and quorum, who hold sessions for the trial of petty offences. The number of counties in England is forty, and in Wales twelve; making in all fifty-two. The following statistical table, collected from various sources, will be found to concentrate a general view of the extent, population, employment, and wealth of each county:—

Counties.	Square Miles.	Houses 10% and upwards.	Rental of Houses.	Population 1831.	Income in 1814-15 arising from				Poor Rates 1830.	Cities and Towns.
					Land.	Trade.	Offices.	Mineral Produce.		
Bedford -	430	723	£12,619	95,383	£364,276	£94,796	£1,481	-	96,994	Bedford - 6,959
Berks -	744	3,713	83,572	145,289	719,889	299,703	3,217	-	129,533	Reading - 15,595

1692. *The immense local topographical details of England, of which we are now to give a rapid sketch, may be conveniently distributed under the following subsections:—* 1. Southern counties; 2. Eastern counties; 3. Midland counties; 4. Northern counties; 5. Western counties.

SUBSECT. 1. *Southern Counties.*

1693. *Under this head, Kent, Surrey, Sussex, Berkshire, Hampshire, Wiltshire, and Dorset, the counties south of the Thames, and along the Channel, will be comprehended. This fine district is, in general, of that level character which is common to the greater part of England. It is traversed, however, by ranges of low hills or downs, which, without producing the greater effects of landscape, give to it a varied and picturesque aspect. Chalk is a predominant feature in its soil; and, on the coast, forms those bold and romantic cliffs, which characterise the southern boundary of Britain. Many tracts are under high cultivation, yielding, in perfection, the usual agricultural products, with others of great value, peculiar to this district; particularly hops, in Kent, and part of Sussex and Surrey. A very prominent feature consists of large expanses of downs, composed of chalky soil, scarcely fit for the plough, but pastured by vast flocks of sheep. This division contains several ancient and venerable cities; but not being supported by any extensive manufactures, they are small in comparison with the immense towns of western and northern England. On the coast are a number of ports delightfully situated, to which the inhabitants of the metropolis resort in crowds, during the summer months, to obtain the benefit of bathing, to inhale the sea-breeze, and enjoy the view of rural and marine scenery. The vicinity of the metropolis, and its own agreeable aspect, has caused this district to be covered with an unusual number of fine and ornamented seats, many of which are enriched with the choicest productions of the arts. Among its other striking characteristics are the great naval docks and stations; whence issue the fleets that support the maritime power of England. These immense public works are situated in Kent, at the mouth of the Thames and Medway; and in Hampshire at Portsmouth.*

1694. *Kent is the largest and finest of these counties. From its position it has ever been regarded as the key of England, connecting that kingdom with the Continent; whence it holds a conspicuous place in her annals. The men of Kent have been noted as a race peculiarly stout, hardy, and courageous. The surface and soil are remarkably diversified. In the west it contains extensive wealds imperfectly reclaimed from the state of continued forest, and presenting still many finely wooded districts; also large marshy tracts, interspersed, however, with dry cultivated portions, in which the best grain in the kingdom is raised. The interior around Maidstone and Canterbury forms almost a continued garden, supplying fruits for the markets of London; and above all, hops, that essential ingredient in the staple beverage of the English nation. Hops, both as to growth and trade, give rise to much speculation; their culture involves great expense in forming poles for the plants to twine round, in clearing and manuring the ground, and in picking them: the price fluctuates from three to fifteen pounds a hundred weight. Seeds, and some wood for dyeing, are also Kentish products.*

1695. *Canterbury, the chief though not the largest place in Kent, is, perhaps, the most ancient and venerable of the English cities. It is the ecclesiastical metropolis of the kingdom, the residence of its primate; who, as such, places the crown on the sovereign's head, and ranks next in dignity to the royal family. Its cathedral (fig. 139.) is of early origin and*

139

CANTERBURY CATHEDRAL.

of vast extent; and if it does not display the same harmonious grandeur as those of York, Westminster, and some others, it is as richly ornamented, and instructively exhibits the various styles of architecture peculiar to those successive periods during which it was built and enlarged. While it was revered through the Catholic world as the shrine of the murdered Becket, it was visited by crowds of illustrious pilgrims, and enriched with the most precious offerings; but of all these treasures it was stripped by the reforming and rapacious hand of Henry VIII. The castle and the strong walls of the city have mouldered away;

but Canterbury retains many traces of its ancient dignity. It is built in the form of a cross, and intersected by branches of the Stour. Manufactures of cloth, silk, and cotton were early introduced, and still subsist, though they cannot now bear a comparison with those of the great towns of the interior and of the north.

1696. *Maidstone and Tunbridge* may also be reckoned among the agreeable inland towns in Kent. The former, of great antiquity, has one of the most extensive and elegant parochial churches in the kingdom. It is the chief market for hops; and has some considerable manufactures, particularly of paper. Tunbridge Wells, situated five or six miles from the town of Tunbridge, have long been a place of public resort. The springs, discovered in the reign of James I., were considered very efficacious in cases of debility and certain chronic disorders. This watering-place, like others, is no less frequented for pleasure than for health, having a double attraction in the purity of the air and the varied features of the surrounding scenery. Every thing has been provided which could render it a commodious and agreeable abode; a handsome bathing-house, a row of fine lime trees, and a covered portico running along the principal promenade; an orchestra, theatre, &c. The town has also a thriving little manufacture of what is called Tunbridge ware, consisting of various wooden ornaments, snuffboxes, tea-chests, dressing-cases, and children's toys.

1697. *But the chief places of Kent are maritime*, the most ancient being those called *the Cinque Ports*. At an early period, they were considered the most important stations for the defence of the kingdom, and invested with corresponding duties and privileges. They were bound to furnish and equip fifty-seven vessels, each manned with twenty-one sailors; in return for which, their citizens held the rank of barons, occupied a distinguished place at the ceremony of the coronation, and sent two members to parliament from each port. Their greatness is now departed. Of their harbours, some have been filled up by an accumulation of sand; and all the great naval depôts of the kingdom have been established in other quarters.

1698. *The Kentish Cinque Ports are Dover, Sandwich, Hythe, and Romney.* The first, as the point at which two mighty and long hostile kingdoms directly face each other, is still a place of considerable note. The spacious castle on a commanding eminence, the white and towering cliffs, present to the approaching mariner an imposing spectacle. As the main channel of communication with France, it maintains twenty-seven packets in constant service. Considerable exertions have been made to repair and improve the harbour, which admits vessels of 400 or 500 tons. Dover shares also in the general resort from London for the purpose of bathing. Folkestone, its dependency, has a considerable fishery of mackarel. Romney and Hythe are now of little maritime importance, though the former is noted for its adjacent territory of 50,000 acres, preserved by embankment from inundation, and now covered with the richest pasture. *Sandwich*, situated on the east coast, though retaining still about 8000 tons of shipping, unquestionably yields in importance to its nominal dependencies, Deal, Margate, and Ramsgate. Deal derives its prosperity from the vicinity of that fine anchorage, the Downs, where the outward-bound fleets of England usually remain for a certain period, when they obtain supplies and refreshments from Deal. It is a bustling, crowded, dirty seaport. Margate, of all the bathing-places to which the citizens of London resort, is the most crowded, though not the most fashionable. If its vicinity does not abound in picturesque beauty, its pier affords an agreeable marine promenade, and the establishment of steam-packets allows daily and speedy intercourse with the metropolis. It carries on also some trade with the

140

DOVER CASTLE.

Baltic, and supplies the metropolis with grain and fish. Having risen within the last half century, it is built with regularity and elegance, and contains twelve marble baths, into which the sea-water is admitted for those who prefer that mode of bathing. Ramsgate, situated on the isle or rather peninsula of Thanet, is also frequented with the same view, possessing the advantage of a very smooth and extensive beach. Considerable improvements have been made in the harbour at the expense of government, with the view to its yielding protection to vessels navigating this coast, where the dangerous shoals of the Goodwin Sands have often proved fatal. Between Margate and Ramsgate is Broad Stairs, also a considerable watering-place. Proceeding up the Thames, we come to those vast *works and depôts* belonging to that navy which has rendered Britain the mistress of the seas; these are—

1699. *Deptford, Woolwich, Chatham, and Sheerness; the grand establishments for the construction of ships of war.* Deptford contains also the Victualling Office, a department of immense extent in time of war. Woolwich is the depôt of artillery, and the theatre of all the operations connected with its construction and preparation. The first view of its grand park, and a large plain completely paved with cannon, strikes every beholder with astonishment. Here is also the Royal Military Academy, in which about an hundred young men of respectable family are trained in all the branches of knowledge necessary for the engineering department; and who, after a strict examination, are appointed to commissions in the service. Chatham is the grand magazine of naval stores, which are kept in the most perfect order in its immense warehouses. The rope-house is 1128 feet long, in which cables 101 fathoms in length, and upwards of two feet in circumference, are constructed. Twenty forges are constantly employed in the fabrication of anchors, some of which are five tons in weight. Great labour and expense have been employed in fortifying this important post, which, with the exception of Portsmouth, is now the strongest in Britain. *Sheerness*, on the Isle of Sheppey, is a smaller station, chiefly employed in the repair of shattered vessels, for receiving which its situation at the mouth of the Medway is very commodious.

1700. *Greenwich*, about two miles below Deptford, is celebrated for its superb and extensive hospital (*fig. 141.*)

141

GREENWICH HOSPITAL.

pensions to 5400 in different quarters of the kingdom. On a hill in the centre of Greenwich park stands the celebrated observatory, furnished with the best instruments that can be obtained for perfecting those observations by which British vessels are guided through the most distant seas. Nor has it served only this practical

for disabled and superannuated mariners. This edifice was begun by Charles II., on a design of Inigo Jones, as a royal palace, in which character it may be said to possess a grandeur which has not perhaps yet been equalled. It remained unfinished and neglected, until the reign of William III., when government determined to convert it into a naval hospital; in which view another wing was added, upon the design of Sir Christopher Wren. Two others were built by Queen Mary and Queen Anne, and the whole four now enclose a grand and extensive square. The hospital, enriched by successive donations from government and from individuals, and by a tax of 6d. a month from every seaman, now supports 3000 boarders, and pays

purpose, but has been the means of advancing, in a remarkable degree, the knowledge of mankind respecting the system of the universe. The recorded observations of Flamsteed, of Halley, of Bradley, and of Maskelyne, have ranked among the most important contributions to astronomical science.

1701. *Gravesend*, situated on the Thames, where it assumes nearly the character of an arm of the sea, has much occupation in the conveyance of passengers by boats to London. Here also the vessels employed in foreign commerce, both in going up and down, must stop and undergo an examination. Near Gravesend is Rochester, a neat town, with an ancient cathedral, containing in its vicinity numerous seats, among which may be particularly noted the fine grounds and mansion of Cobham Hall, which Lord Darnley has adorned with a valuable collection of paintings and sculpture. Lee Priory is also remarkable for its works of art; and Knowle Park forms a magnificent castellated structure of great extent, and adorned with numerous portraits.

1702. *Sussex*, west and south of Kent, extends about forty miles along the Channel. It is covered to the extent of 170,000 or 180,000 acres with those noble oaks which once overspread the whole county, and are still sought in preference to any other for the use of the royal navy. There are extensive downs fitted only for the pasture of sheep, of which the Sussex breed is peculiarly valued both for mutton and wool.

1703. *Of cities and towns*, the capital is Chichester, an ancient little city with rather a fine cathedral. Winchester, Rye, and Hastings are Cinque Ports. The former has lost almost all its ancient importance, and presents scarcely any thing but ruins. Rye also is much reduced; but Hastings, from the fine views of land and sea, obtained from various spots in its vicinity, has attracted numerous visitants during the summer, and by the increase of new buildings seems to have become a favourite residence. In this respect, however, it is far surpassed by Brighton, which the sojourn of royalty during a considerable period rendered the gayest of all the southern watering-places. From being a large fishing village of some antiquity, it rapidly rose to be an elegant town, filled with commodious houses. Its environs present nothing particularly striking; but an extensive lawn called the Steyne, sloping towards the sea, forms an agreeable promenade. The Pavilion, or palace built by his late majesty, in this favourite spot, has been the subject of controversy as to its architectural taste; but none can withhold from it the praise of agreeable variety of effect, and all must acknowledge the splendour with which it has been furnished. Towards the sea, the chain pier is the distinguishing feature of Brighton, and affords great convenience to the packets between this port and those of France. Arundel, on the Arun, is rather a thriving port, whence a good deal of timber is exported. In all the ports of Sussex, there is a considerable fishery, particularly of mackarel, for the London market.

1704. *Surrey* fills up the inland space between Sussex and the Thames. Its aspect is various. The rough downs and bleak heaths which cover so much of the south of England, are here peculiarly extensive. These rude and often bold features, contrasted with the numerous fine parks and wooded districts, give to its scenery a striking and picturesque character. Their influence, however, on its productiveness, is much less favourable; and, notwithstanding the encouragement afforded by the vicinity of the metropolis, the agriculture is supposed to be less advanced than in other parts of the kingdom. Though the great impulse of the last thirty years has had the effect of reclaiming a considerable portion, there are supposed to be still upwards of seventy thousand acres almost entirely waste. Southwark is in Surrey; but it is too entirely a part of London to be treated separately from the rest of that capital. Guildford, Godalming, Croydon, Ryegate, Dorking, are neat pleasant little towns. The last in particular, placed in the most variegated part of the downs amidst eminences crowned with fine seats, is one of the pleasantest retreats in England. Along the southern bank of the Thames are likewise many fine spots: Kew, with its palace and fine gardens, containing valuable and curious plants from every quarter of the world; Richmond and its hill, which commands so expansive and magnificent a view of the Thames winding among wooded parks and palaces. Camberwell, Clapham, and other villages in the immediate vicinity of the capital, wear a very gay aspect, being entirely composed of the ornamented villas of opulent citizens. Surrey has also for the supply of London a great extent of garden ground, and many acres covered with various medicinal and aromatic plants. The *seats* are numerous and fine, but none very prominent, except the royal residences already mentioned, with Claremont Park, so interesting as the favourite abode of the late Princess Charlotte, and St. Anne's Hill, a beautiful villa on the Thames, where Mr. Fox passed many of the latter years of his life in literary retirement.

1705. *Berkshire*, continued westward from Surrey, occupies the whole southern bank of the Thames as far as Lechlade, where that river first assumes an important character. The chalk range is continued through the southern part of this county, rendering it fit only for sheep pasture; and a great expanse of its eastern border is occupied by forests, the principal of which is that of Windsor. Notwithstanding these deductions, more than half its extent consists of fine arable land. It sends to London a great quantity of excellent flour, and also of malt. The sheep fair of Ilsley is reckoned the most considerable in the kingdom, the annual number sold averaging two hundred and fifty thousand. The hogs also of this county are in high repute. Berkshire has the advantage of being watered by the Kennet and several tributaries to the Thames, and also of being traversed by two canals, the Berks and Wilts, and the Kennet and Avon. The cloth fabrics, however, which a century ago were considerable, have disappeared; and it is now only remarkable for the manufacture of copper into sheets and bolts, by mills, which are esteemed the most complete and powerful in the kingdom. The metal is brought from Swansea to the annual extent of six hundred to one thousand tons.

1706. *Reading*, the capital of Berkshire, is a place somewhat remarkable in history, as several parliaments were held there, and a siege of considerable length was sustained during the period of the civil war. It still enjoys some prosperity, through the residence of a number of wealthy families, and the export of the rich produce of the fertile surrounding district.

1707. *Windsor*, however, is the pride of Berkshire, both from the beauty of its site, on an eminence near the Thames, and the magnificence of its royal castle (*fig.* 142.), which crowns the summit and forms a commanding

feature in the prospect for many miles around. The site both of town and castle were granted by Edward the Confessor to the abbey of Westminster; but William I. exchanged it for some lands in Essex, and constructed

142

WINDSOR CASTLE.

here a fortress of considerable size. Henry I. greatly enlarged the building, and erected a chapel. Other additions were made by succeeding sovereigns; but the whole structure was re-modelled by Edward III. Since it ceased to be important as a place of strength, it has been occupied as a palace; and is the only one, in fact, suitable to the dignity of the monarch. Queen Elizabeth formed a terrace walk on the north side of the castle; and Charles II. extended this noble promenade round the east and part of the south front. It is 1870 feet in length, and commands a finely varied and extensive prospect. The same monarch injured the style of the structure by introducing circular French windows, instead of the Gothic ones; but his alterations of the interior were in better taste. George III. completely repaired St. George's chapel, and partly restored the north front of the upper ward to its original appearance; but in consequence of his illness, the other improvements were suspended for eleven years. George IV. resumed them on a scale commensurate with the importance of so venerable and magnificent an edifice; and large sums of money were voted by parliament for this national purpose. The most distinguished architects in England were competitors for the execution of the work; but the plans of Mr. (afterwards Sir Geoffrey) Wyattville were finally determined on, the commissioners being the Duke of Wellington, the Earls of Liverpool and Aberdeen, Lord Farnborough, and Mr. Baring. Among the external improvements was that of raising the buildings on the south and east sides of the quadrangle, and lowering the area, removing Augusta Lodge, and Queen's Lodge, forming a new entrance gateway opposite the long walk in Windsor Great Park, which forms a noble approach. East of the gateway is York Tower, and another to correspond was founded on the west side by George IV., and called Lancaster Tower. Immediately opposite this gateway is the principal entrance to the state apartments. A corridor extends round the south and east sides of the building, and forms a fine promenade when the weather is unfavourable for out-door exercise. At the south-east angle is the king's private entrance. On the east side of the archway opening into the quadrangle is a small tower; in front of the entrance are the royal arms in basso-relievo. Folding doors at intervals open into the various apartments; those on the east being appropriated to the king; those on the south to the household. The royal apartments have fine oriel windows, and are exquisitely finished; they are fire-proof, the floors being of brick, and the girders iron. On the exterior near the eastern angle of the terrace an octagonal-shaped tower has been erected, called Brunswick Tower. Another improvement on this side is a pentagon terrace, with bastions at the angles, extending into the park, and communicating with the old terrace on the north and south sides. The alterations on the south front are confined to the new gateway, and the raising of the building to a level corresponding with the interior of the quadrangle. On the north side a communication is established between Brunswick Tower and the state apartments by a corridor terminating at the king's guard-chamber, where a new tower has been erected, called George the Fourth's tower. The royal apartments contain an extensive collection of paintings of various degrees of excellence, among which are some fine portraits by Vandyke, and some historical pictures by Guido, Correggio, Carlo Dolci, and Leonardo da Vinci. The chapel of St. George is considered one of the finest specimens of the ornamented Gothic in the kingdom. The choir in particular is of admirable workmanship, and adorned with banners of knights of the garter ranged on each side. It includes also the tombs of many of the English princes, particularly their late majesties, and the Princess Charlotte; and some of its windows are painted with considerable beauty by Jervis and Forrest, after the designs of Reynolds. To the south of the palace extend Windsor Great Park, and Windsor Forest, grand features, first formed by William the Conqueror, in his fixed determination to enjoy, at whatever cost, the pleasures of the chase. Even after the considerable abridgment that has taken place, the domain is still fifty-six miles in circumference, containing within its range some noble timber. Parts of it were devoted by George III. to his favourite and useful pursuit of experimental farming.

1708. *The other towns of Berkshire* are small, but ancient and neat. Abingdon, Farringdon, Newbury, once the seat of a great woollen manufacture, and where two obstinate battles were fought in 1643 and 1644. Maidenhead (formerly Mainhithe), on the the Thames, is beautifully encircled with villas.

1709. *Seats.* Frogmore, the neat small palace of the late Queen Charlotte, surrounded by fine retired gardens. Park Place, near Henley-on-Thames, the grounds of which are very beautiful. There are also numerous fine villas on a smaller scale.

1710. *Hampshire*, between Berks and the sea, is a fine and important county. Here are the extensive remains of those grand forests which once overspread so great a part of England. The principal is the New Forest, covering the whole south-western part of the county, bordering on the Channel and the bay of Southampton. From this tract of about 92,365 acres, the ruthless tyranny of William the Conqueror drove out all the wretched inhabitants, and demolished the parish churches, that the royal sports might be carried on undisturbed. The forests of Bex, Holt, Alice, &c., containing upwards of 30,000 acres, belong also to the crown. The wood is chiefly oak and beech; the former with a short thick trunk and strong crooked branches, rendering it of excellent service as knee timber for the navy. The extent of these forests, with their many-coloured foliage, and the deep glades and cultivated tracts intervening, exhibit all the varieties and beauties of forest scenery. Numerous herds of royal deer traverse their recesses; while its masts, acorns, and other pro-

duce, are most beneficially appropriated to feeding hogs in great number and of vast size, weighing sometimes eight hundred pounds, and producing the best bacon in the kingdom. The chalky downs that traverse the county are not such as to render it rugged or sterile; they every where afford excellent pasture for sheep, and are even capable, with good management, of being brought under the plough. Many of the valleys are very rich, and the system of management is good; so that Hampshire is altogether a very productive province.

1711. *Winchester* claims precedence over Southampton as capital of Hampshire; and is, perhaps, the most ancient and venerable of all the cities in England. During the greater part of the Saxon period, it ranked as the metropolis of the kingdom. It had at one time upwards of ninety churches and chapels, with colleges and monasteries attached to them. Being frequented on account of its fairs, and chosen as one of the staples for wool, it became at one period the seat of a very extensive commerce. After the Norman conquest, when London became gradually the royal residence, the decline of Winchester commenced, and was accelerated by the removal of the wool trade; but above all by the dissolution of the monasteries, in the time of Henry VIII. It suffered also during the civil wars; and now owes its chief importance to its rank as an episcopal city, and a county town in which assizes are held alternately with Southampton. Its venerable cathedral (*fig. 143.*) has been the work of successive ages. It was founded under the Saxon kings, and part of what was built by Ethelwold is still remaining. It was then enlarged by Bishop Walkenlin in the eleventh century, and still more by William of Wykeham under Edward III. The completion is ascribed to Bishop Fox, in the beginning of the sixteenth century, when extensive additions were made to it in the highly ornamented and pointed English style; of which several of the specimens here preserved are reckoned the finest in the kingdom. The college, or rather school, founded by Bishop Wykeham is also a magnificent edifice, especially its chapel and hall. It has always maintained its reputation, and is one of the four great classical schools to which the distinguished youth of England resort. Southampton now surpasses Winchester, and is a gay and flourishing town; at the

head of the bay or estuary called Southampton Water. In the Saxon period it was called Hanton or Hampton, and gave name to the county; it afterwards declined, but has since revived. It carries on a considerable trade with the south of Europe, and with Jersey and Guernsey; and regular packets sail from it to Havre de Grace. It is also supported by the resort of strangers for the purpose of bathing, and of visiting the romantic scenery of the New Forest and the Isle of Wight.

1712. *Portsmouth*, however, now eclipses in magnitude all other places in Hampshire; being the grand arsenal for equipping the powerful navies of Great Britain. No port in this country,

or perhaps in the world, affords a greater combination of natural advantages. The harbour is formed by a considerable bay, with a commodious entrance, perfectly landlocked, and sheltered from every wind, affording secure anchorage all round; and capable from its dimensions of containing the whole British navy. The Isle of Wight, opposite and parallel to the English coast, forms at its eastern extremity the safe and magnificent road of Spithead, which has so long formed the principal rendezvous of the national fleets. Every thing has been done by art to improve these natural advantages. The place has been strengthened by successive fortifications, particularly by immense batteries on the sea-side, till it has become the strongest and most finished fortress in the empire, and is considered absolutely impregnable. Portsmouth itself is situated on an island about fourteen miles in circumference, separated from the land only by a narrow channel. The suburb of Portsea, on the same island, begun only a century ago, has now outgrown the original town, and contains the principal dockyards. Here are carried on, upon a gigantic scale, all the operations subservient to building, equipping, and refitting ships, and supplying the navy. The sea-wall of the dockyards extends nearly three quarters of a mile, and encloses an area of one hundred acres: the forge, where, with tremendous and stunning noise, anchors of huge dimensions are formed, and the wharf on which they are piled; the ropery, above a thousand feet long; the spacious dry docks; the endless range of warehouses; the gun-wharf; the armoury, are all objects which astonish by their immensity. The intelligent spectator is highly gratified by the displays of ingenuity made in various processes, as the making of ropes, and particularly machinery for cutting blocks. From its destination, Portsmouth was not very likely to become an elegant town; yet it contains several handsome structures for the residence of the government officers, as well as for religious purposes.

1713. *The other towns of Hampshire* do not want interest. Christchurch, at the western extremity, is noted for a curious and fine ancient church. Lymington, a small seaport, is the real capital of the New Forest, though that title is given to the village of Lyndhurst; while Beaulieu with the ruins of its venerable abbey, is placed in the centre of its most beautiful scenery. Andover, Basingstoke, and Romsey are considerable towns, employed in the trade of grain and provisions, and manufacture some druggets and shalloons.

1714. *The seats are numerous*, as Avington, Stratton Park, Broadlands, Cuffhells, most of them finely situated, and adorned with paintings of considerable value; the last has a fine library.

1715. *The Isle of Wight* ranks as part of Hampshire; but it is so separated, and has features so peculiar to itself, that we keep it distinct. This fine island is about twenty-three miles in length, and thirteen in breadth; divided by a channel of only a few miles from the opposite coast of England, on which are the bays of Portsmouth and Southampton. It is traversed by a ridge of the same chalky downs which prevail in southern England, in which

WINCHESTER CATHEDRAL.

are fed about forty thousand fine-woolled sheep of the Dorsetshire breed. On the north of these downs, however, are luxuriant meadows, supporting valuable breeds of horses and cattle; while on the south are fine arable plains, yielding grain much beyond the consumption of the island. The myrtle and vine flourish in the open air, which is rendered fragrant by numerous other plants and flowers. The island, however, is chiefly celebrated for its striking and peculiar scenery; the grand views of land and sea enjoyed from its high open downs; the deep and dark ravines of its southern shore, and the bold romantic cliffs which it there presents to the expanse of the English Channel. One of the most conspicuous features is the range of coast called the Undercliff. "Bold cliffs," says Mr. Windham, "low lands or declining shores, are the usual boundaries of the ocean; but here a wall-like precipice of lofty rock extends about a mile from the sea: in this interval of rock and water, colossal fragments of stone, torn or sunk from the precipice, are scattered below in the most irregular confusion. These masses are of such ponderous magnitude, that they form high eminences of the most capricious shapes, while their intermediate spaces become deep valleys, in which houses are built, and even ash trees and elms are seen to flourish, sheltered from the storms and spray of the sea by the hospitable and lofty shades of the fragments." This district, when viewed from the sea, presents the appearance of a series of gigantic steps rising from the shore, itself steep, to the summit of the great perpendicular wall. The *chines*, or chasms, with torrents bursting through them, are also characteristic features. The most picturesque is that of Shanklin, the opposite sides of which, about three hundred feet high, approach each other till they leave scarcely space for the rivulet to penetrate; and are grotesquely lined with shrubs, bushes, and a few trees. Farther to the east, immediately under St. Catherine's Hill, the highest spot on the island, is Blackgang Chine. Two rapid torrents here roll through separate chasms, till, uniting, they form a stream of much greater breadth, and at a short distance the whole body of water rushes down a rock forty feet high. This chine has nothing of the gay and ornamented appearance of that of Shanklin. Not a shrub clothes its sides, composed only of rugged and mouldering rocks; the whole scene is dark, grand, and awful.

1716. *The western part of the Isle of Wight* presents also very striking objects. At its farthest extremity rises a succession of rugged and pointed cliffs, called the Needles; an object of some danger to the mariner, though of admiration to the curious spectator. Fifty years ago, one of these, which rose to the height of 120 feet, fell, with a crash which shook the whole island, and was felt as far as Southampton; and no vestige of it has ever since been seen above the waves. Westward extends Allum or Freshwater Bay, presenting a range of magnificent white cliffs, rising perpendicularly to the height of 500 or 600 feet. These dreadful precipices are inhabited by gulls and puffins, the eggs of which are taken by the daring islander, suspended in a basket, which is fixed by a rope to the summit. Several large cavities occur, particularly that called Freshwater Cave, which opens with great magnificence, and forms two arches having their sides covered with moss and weeds, and the entrance obstructed by large fragments of rock.

1717. *The eastern shore of the isle*, where it faces the Channel, presents the Culver Cliffs, a range of precipices which, in grandeur and ruggedness, are not surpassed by any other on the island. The coast, however, which ranges along the bay of Spithead is diversified only with gentle hills; and the chief interest is in viewing those immense ranges of shipping which fill that road and the opposite haven of Portsmouth.

1718. *The castle of Carisbrook*, in the very centre of the island, is an ancient edifice, in which the unfortunate Charles I. was for some time imprisoned. It appears to have been built by William Fitz Osborne, about the time of the Conqueror, but was enlarged by successive owners, and particularly by Elizabeth. The walls were at one time three quarters of a mile in circumference, surrounded by a deep ditch, and considered in those days as impregnable. Even in its state of progressive decay, it presents a curious specimen of Gothic architecture, as well as a striking monument of baronial grandeur.

1719. *The towns of the isle* are small and neat. Newport, in the interior, derives its principal support from travellers, to whom it serves as a central resort, on proceeding to the different points on the southern coast. It has also a manufacture of biscuits for the navy. Yarmouth, Cowes, and Ryde, are agreeable seaports, to which packets sail from Lymington, Southampton, and Portsmouth. The villas of Lord Henry Seymour and of Mr. Nash at East and West Cowes are particularly admired.

1720. *Proceeding along the southern counties, we come to Dorset.* It consists, still more than those already described, of open chalky downs, fit only for sheep, which are here of a breed called the Southdown, peculiarly fine both as to carcass and wool. The Southdown sheep (*fig. 144.*)

SOUTHDOWN SHEEP.

are without horns; they have dark or black-grey faces and legs, fine bones, long small necks; are low before, high on the shoulder, and light in the fore quarter; the sides are good, and the loin tolerably broad, back-bone too high, the thigh full, and twist good. The fleece is very short and fine, weighing from $2\frac{1}{2}$ to 3 lbs. The average weight of two years' old wethers is about 18 lbs. per quarter, the mutton fine in the grain, and of an excellent flavour. These sheep have been brought to a high state of improvement by Elman of Glynd, and other intelligent breeders. They prevail in Sussex, on very dry chalky downs, producing short fine herbage. The number fed is estimated at 800,000, producing 2,790,000 pounds' weight of wool. A considerable

quantity of hemp and flax is also produced, and employed in pretty extensive manufactories of ropes, sacking, &c. Here also a vast number of women and children are maintained by the making of shirt buttons. The islands of Purbeck and Portland are valuable for the production of fine freestone, an article generally wanting in the east and west of England; and therefore largely exported for ornamental edifices in the great cities, particularly London.

1721. *Dorsetshire has no very remarkable towns.* Dorchester, its capital, is well built, and contains a county jail, formed on the plan of Howard. Poole, with an excellent harbour, carries on trade with the Baltic and with Newcastle, sends vessels to the Newfoundland fishery, and has a considerable export of pipe-clay. Weymouth has lost its trade, but is finely situated for a bathing-place, in which capacity it has been much frequented, especially since George III. made it his favourite resort during the season.

1722. *The principal seats.* Sherborne Castle, the residence of the Earl of Digby; rather a fine old mansion; formerly occupied by Sir Walter Raleigh. Lulworth Castle. Milton Abbey, the residence of the earls of Dorchester. Corfe Castle, an ancient fortress of great strength and extent, where Edward, king of the West Saxons, fell a victim to his mother-in-law, Elfrida. It is now uninhabited, and a complete ruin, having been blown up by order of Oliver Cromwell.

1723. *Wiltshire*, which concludes our southern list, is a large and fine county, which almost approaches to the character of the western manufacturing districts. The long range of chalk hills here terminating, forms that large table land which separates the county into two divisions, called North and South Wilts, and is termed Salisbury Plain; a vast, naked, undulating surface, which affords pasturage for sheep. The northern part of Wiltshire, watered by the Thames, is chiefly underwood and pasture, and supports a valuable breed of cattle, from whose milk is made the excellent cheese bearing the name of the province. The arable land does not much exceed a fifth of the whole extent. Wiltshire is a manufacturing county. The woollen fabrics, in quitting the southern districts, where they once generally flourished, have remained here to a considerable extent. There is not, as in the north, any metropolitan seat of the manufacture; but a number of flourishing little towns carry it on separately. The produce is of the finest description; superfine broadcloth, kerseymeres, and what are called fancy articles; to which we may add, fine flannels at Salisbury, and at Wilton the carpets which bear its name, and rank next to those of oriental manufacture. There are also, in detached places, some cutlery, linen, and cotton, though not on a great scale.

1724. *Salisbury*, the capital of Wiltshire, though not of very great extent, is a handsome and well-built town. The streets are spacious and regular, crossing each other at right angles, and kept extremely clean by streams of water, derived from the river Avon, running through each. These channels were formerly open, but are now mostly covered in. The pride of Salisbury is its cathedral (*fig. 145.*) commenced in 1219, and completed

SALISBURY CATHEDRAL.

in 1258, which, though it may not possess the imposing grandeur of York Minster, is considered the most elegant and finished Gothic structure in the kingdom, and at the same time the most regularly built, having been founded after the demolition of the very ancient cathedral of Old Sarum. It has also the loftiest spire, rising to the height of four hundred and ten feet. The chapter-house is universally admired, and contains some curious specimens of antique carving in stone. Salisbury was formerly noted for its flannels and cutlery, but both these have declined. It is a place of much resort, not only from its importance as the county town, but from the vicinity of numerous seats of the nobility and gentry.

1725. *Old Sarum*, or the locally denominated Old Castle, exhibits on the summit of a hill traces of the ancient fortress of the earls of Salisbury, which have a very singular and imposing appearance, though scarcely a fragment of the walls has been left.

1726. *Wiltshire has a number of neat thriving little towns*, in which fine woollen manufactures are carried on with activity: Devizes, Marlborough, Chippenham, Malmsbury, Warminster, Wilton, &c. Most of them are pretty ancient, and adorned with fine old churches.

1727. *Stonehenge* (*fig. 146.*), near the little town of Amesbury, in a corner of Salisbury Plain, is the most remarkable monument of antiquity in the island, and now supposed to be the remnant of a temple of the Druids. "It consists," says Mr. Sullivan, "of the remains of two circular and two oval ranges, having one common centre. The outer circle

is one hundred and eight feet in diameter, and in its perfection

146

STONEHENGE.

consisted of thirty upright stones. The upright stones are from eighteen to twenty feet high, from six to seven broad, and about three feet thick; and being placed at the distance of three feet and a half from each other, are joined at the top by imposts or stones laid

across. The inner circle is somewhat more than eight feet from the inside of the outward one, and consisted originally of forty smaller stones; of which there are about nineteen left, and of these only eleven standing. The walk between these circles is three hundred feet in circumference; and from this walk the structure has a surprising and awful effect." In the interior of all are two oval ranges, supposed to be the principal part of the work, composing the cell or adytum. The stones that form it are stupendous, some of them measuring thirty feet in height. The whole number is computed to have been originally one hundred and forty.

1728. *No county in England, perhaps, is adorned with so many and such fine seats as Wiltshire.* Wilton House, "Pembroke's proud domain," with a fine front by Inigo Jones, is classed by Mr. Young as one of the four which might rank as palaces. It contains the finest private collection of ancient sculpture in the kingdom, also numerous paintings, of which some are valuable. Corsham House and Longford Castle contain celebrated collections of pictures. Wardour Castle is distinguished for its grand terrace, commanding a noble view; and Stourhead for the romantic beauty of the grounds: both these residences contain valuable paintings. Longleat is a superb seat, adorned with a most extensive collection of English portraits. Fonthill once surpassed them all in fairy and fantastic splendour; but it is now a ruin.

SUBJECT. 2. *The Eastern Counties.*

1729. *Under this title are comprehended the counties of Essex, Suffolk, Norfolk, Cambridge, Huntingdon, and Lincoln.* Level as the surface of England generally is, that of these districts is, beyond all others, flat and unvaried. This great lowland of England scarcely rises above the sea in its eastern boundaries. The mariner discerns its existence only by a dark line, above which a tower or steeple occasionally rears its head. Its sluggish streams unite in the shallow marshy estuary of the Wash, which divides this region into two unequal parts. A great proportion of its waters, however, never reach that receptacle; but, spreading and stagnating over the land, form what is called the Fens, a tract which is not unproductive to the husbandman, but sends forth pestilential vapours, subjecting the inhabitants of the surrounding districts to perpetual attacks of fever and ague. It must not be omitted, however, that the active spirit of modern husbandry has done much to drain these waste tracts, rendering them at once more productive and healthy. These districts contain wide portions of good arable land, which are well cultivated by skilful farmers with large capitals, who find a ready market in the metropolis. Generally speaking, the district is most noted for its breeds of cattle, some of which are very valuable, and for the products of butter and cheese. There are seats, and some of the greatest magnificence, but they are not so numerous as in the south, and rather attached to property than chosen for felicity of situation.

1730. *Essex*, situated along the north of the Thames, is, perhaps, the richest of the English counties. It is not a dead or swampy bed, but diversified by gentle undulations, which do not interrupt the careful culture given to its rich alluvial soil. Its wheat, with that of Kent, is reckoned the best in England; but the districts closely approaching the metropolis are chiefly in pasture, or artificial grass, for supplying calves to the London market, or for fattening the cattle brought up from the north. There are some woollen manufactures, but of no great consequence. At the mouth of the Colne, Blackwater, and other rivers, about 200 vessels are employed in dredging for oysters, of which they are supposed to send to London about 20,000 bushels annually.

1731. *The towns of Essex* are not very conspicuous. Chelmsford, the county town, is a small regularly built place, with a handsome town-hall. Colchester, nearly triple in size, is supposed to be the ancient Camulodunum, and contains in fact a strong castle, said to have been founded by the Romans. It is supported by a manufacture of baize, considerable though decayed, and by the oyster fishery. Harwich, a seaport with a deep and spacious harbour, is the place where the government packets, in time of peace, sail for Holland and Germany. It is a gay place, convenient for sea-bathing, and surrounded with agreeable scenery.

1732. *Seats.* Wanstead House, considered by Mr. Young as one of the noblest houses in England, is now demolished. Audley-end has fine grounds, and some good pastures. Mirtley is beautifully situated. Many other villas have been erected in this county, in consequence of its vicinity to the metropolis.

1733. *Suffolk*, north of Essex, is almost an inland county, bordered by only a small proportion of eastern coast. Though considerably encroached upon by the fens, and though some of the tracts on the coast are sandy, by much the greater part of it is capable of good cultivation, and is carefully tilled by substantial and skilful farmers. The cows of Suffolk are famous for their copious supplies of milk, out of which is made an abundance of excellent butter, also plenty of poor cheese from the skimmed milk. The Suffolk breed of horses is also esteemed, and very considerable flocks of sheep are fed on some of the open tracts.

The rabbit, the pigeon, the turkey, also flourish in Suffolk. The county is almost purely agricultural, there being neither trade nor manufactures of any importance.

1734. *Among the towns of Suffolk*, Ipswich is still considerable, though it has lost its once flourishing woollen manufacture, and its employment is confined to sending down the Orwell malt and grain, the produce of the county. Bury St. Edmund's is an ancient town, delightfully situated, and rendered venerable by some fine old churches. Lowestoff, the most easterly point of England, and the most conspicuous feature in the county, stands somewhat romantically on a cliff overlooking the sea, where a large lighthouse has been erected. It is a noted seat of the herring fishery.

1735. *Seats*. There is a great division of property in Suffolk, and consequently it has few seats of the first rank. We may, however, mention Ickworth Hall, the unfinished mansion of the Earl of Bristol. Henningham Hall, a noble seat, is adorned with good Dutch pictures.

1736. *Norfolk*, though inferior in fertility to the two counties now described, has, by its industry, rendered itself more flourishing than either. The sea and the coast of the Wash make a great sweep round it on the north, giving it a large extent of coast. The fens encroach only to a limited extent on its western district; where the soil generally is a light sand, scarcely fit, originally, for any thing but sheep. Beneath, however, is a bed of rich soapy marl, which the farmers, with great labour, dig out, and spread over the ground. Thus was effected a wonderful change; "for," says Mr. Young, "instead of boundless wilds, and uncultivated wastes, inhabited by scarcely any thing but sheep, the country is all cut into inclosures, cultivated in a most husband-like manner, richly manured, well peopled, and yielding an hundred times the produce that it did in its former state." The light sandy loam thus formed is peculiarly favourable to the growth of barley, in which grain two thirds of the country is laid out. The farmers carry on their business on a great scale, and have introduced all the most improved and economical modes of culture. Nor do the "North folk" limit their exertions to the culture of the ground; they carry on with spirit every branch of industry. Norfolk is the only eastern county that has extensive manufactures; it produces various ornamental fabrics of silk and worsted. The ports carry on a very considerable export of grain, and a very spirited fishery.

1737. *Norwich* is the finest city in the east of England. It may be called a seaport, being so near the mouth of the river Wensom that large vessels can come up to its walls. Within the last few years most extensive improvements have been made in this navigation. The chief industry of Norwich, however, consists in manufactures. Towards the end of the sixteenth century, a large colony of Flemings settled there, and established the fabric of woollens, which soon reached an unprecedented height. The light and ornamented forms became the staples; bombasines, crapes, fine camblets, and worsted damask. The woollen manufacture, while it declined in every other part of the east and south of England, continued to advance in this city, though not with the same rapid steps as in the north. Its only severe check was sustained during the late war, from the shutting of the continental ports, for which the Norwich goods had been chiefly destined. Between 1786 and 1801, its population fell from 40,000 to 36,800; but since the peace it has revived very rapidly, having

risen, as above stated, to 61,116. Yet there have been recent complaints of want of employment, chiefly owing, we are informed, to combinations among the workmen. In its general structure, it has the defects of an old town, the streets being narrow and winding, though those recently built are in a more improved style. The chief ornaments, however, are its ancient structures, erected at the earliest eras of British history. The cathedral (*fig. 147.*), founded in the eleventh century, ranks among the very first ecclesiastical edifices in the kingdom. Its style of architecture is the Saxon, of that broad and massive character which prevailed before the introduction of the pointed arch and the light ornamented style. The effect is grand and imposing, though somewhat injured through unfortunate additions made by modern hands. The castle, placed in the centre, is considerably more ancient still, since antiquaries now generally agree in referring it to the reign of Canute. Its style is Saxon; the keep remains entire.

147

NORWICH CATHEDRAL.

1738. *Yarmouth*, by commerce and fishery, has attained a prosperity almost equal to that of Norwich. Situated at the mouth of the Yare, it is the chief channel by which the manufactures of that city are transported to foreign parts. A more important resource is the herring fishery, of which Yarmouth has always been a grand centre; which employs six thousand seamen, and produces annually upwards of fifty thousand barrels. It even derives advantage from the dreadful perils incident to a coast encumbered with sandbanks, that leave only narrow and precarious passages. This induces the small craft from New-

castle and other northern ports to seek shelter in that of Yarmouth, which is excellent and perfectly safe. Its quay, upwards of a mile long, is said to be second only to that of Seville; but the maintenance of the piles by which it is protected, involves an annual expense of 2000*l*. Yarmouth is also much frequented as a watering-place. The church dedicated to St. Nicholas is regularly built, and has an organ said to be superior to any other in this country.

1739. *Of other towns in Norfolk*, the chief is Lynn Regis, a flourishing seaport on the Wash, at the mouth of the Ouse, which, with its tributaries, brings down the agricultural produce of many rich counties. Cromer and Wells are tolerable fishing ports.

1740. *Seats*. Though Norfolk is not generally an ornamented county, it contains several of the most superb seats in England. Foremost stands Holkham, built by Lord Leicester on a design of Inigo Jones, and particularly noted for a gallery room which is considered almost matchless. It is richly adorned with sculpture and paintings, particularly by Claude, and has also a very extensive library, to which the present munificent possessor is daily adding. Houghton is still a magnificent seat, though the collection of paintings, formed by Sir Robert Walpole, and considered the first in the kingdom, was purchased for the Empress of Russia.

1741. *Cambridgeshire* presents a very considerable variety of surface. Its northern district, called the Isle of Ely, intersected by the lower channels of the Ouse and the Nen, exists almost in an intermediate state between land and sea. Their full waters overflowing this dead flat, part of the great Bedford level, a shallow swampy inundation is produced, called *fen*, unfavourable to every produce, except a rank luxuriance of pasture, and causing among the inhabitants severe fever and ague. Drainage, however, to a great extent has been effected during the late period of improvement; many tracts have been converted into fine meadow, or made to yield large crops of oats, though the danger of inundation can never be wholly averted. The classic stream of the Cam or Granta, in descending to join the Ouse, waters a valley called "the Dairies," where some good cheeses and long rolls of excellent butter are prepared for the tables of the Cambridge students. The southern and western districts of Cambridge are encroached upon by the downs from the south, which are filled with calcareous substances, and only fit for the pasture of sheep.

1742. *The capital of Cambridgeshire is the seat of one of the two great universities*. The first origin of this institution is a subject of antiquarian controversy; but, from a deed of Henry III., it appears to have assumed its regular character and functions in 1229. Since that time, have been built the thirteen colleges and four halls, in which the masters, tutors, and students, not only teach and are taught, but are lodged and boarded. Some of the largest of these endowments are stated to be for "poor and indigent scholars;" but this destination is entirely changed, and they are filled with the sons of the most opulent families in the kingdom, who cannot live there but at a very considerable expense. Yet the resort continues to increase, and the existing colleges are insufficient to contain the applicants, who must often wait several years previously to admission. These colleges are large, and generally fine and handsome buildings; yet they do not produce the same noble and imposing effect as those in the sister university. They are not arranged along two grand streets, but dispersed through those of a secondary class, sometimes almost in by-lanes. Cambridge is a busy stirring place, dealing largely in corn, malt, butter, solid and useful objects, not quite in harmony with the refined purposes of this great institution; yet it can boast two single structures such as its rival cannot match. The first of these is the chapel of King's College, (*fig. 148.*), built between the reigns of Henry VI. and Henry VIII.

148

KING'S COLLEGE CHAPEL.

Its interior has been called matchless; and though we could not consider it in sublimity as rivalling that of York, it is certainly more beautiful and more brilliant. The roof is of the most perfect workmanship, and its support without pillars has been viewed as an architectural mystery. But the most striking characteristic is the prodigious blaze of painted glass, on each side, from twelve brilliantly tinted windows fifty feet high, giving to the fabric the appearance of being walled with painted glass. The whole has the aspect, less, perhaps, of a solemn religious edifice, than of a fairy palace called up by the wand of an eastern enchanter. The other very fine edifice is Trinity College, particularly admired for its library, two hundred feet long, designed by Sir Christopher Wren, and perhaps the most elegant library room in the kingdom. The hall is also the largest in Cambridge; and the roof is ornamented with fine specimens of old wood-work. Its chapel is marked by a beautiful simplicity, and contains Roubiliac's statue of Sir Isaac Newton, supposed the best resemblance that exists of that great man. It would be impossible to give even a cursory list of the *admiranda* of Cambridge; but it must not be omitted that great exertions are now making to extend its beauties, and to clear away the obstructions by which they have been hidden from the public eye. King's College, in particular, will, it is said, be completed in all its parts, according to the grand original plan, hitherto carried into effect only in regard to the chapel.

1743. *Among public collections*, the principal library, though it cannot rank with the Bodleian, contains 100,000 volumes, many of which are scarce and valuable. Trinity College, in its ornamented hall, has 40,000. Earl Fitzwilliam, from his seat near Richmond, presented lately a handsome library, some fine pictures, and a large collection of engravings. Valuable manuscripts and antiquities have been presented to the university by its *alumni* who have travelled into foreign countries. The botanic garden is reckoned inferior to none in the kingdom, except those of Kew and Liverpool.

1744. *The great men* who have issued from this university are too numerous for our limits to admit any attempt an enumeration. Since it was adorned by the immortal name of Newton, mathematics and natural philosophy have been the ruling pursuits; and, notwithstanding the lustre reflected on it by Milton, as well as by Bentley and Porson, it has left to Oxford the foremost place in classical knowledge. Among the statesmen who studied here, Cromwell and Pitt may be particularly noted. Cambridge has produced a number of adventurous and distinguished travellers, among whom Browne and Clarke deserve particular mention.

1745. *The population of Cambridge*, amounting, as above stated, to 20,971, is double that in 1801. The resident members of the university in 1801 were 811; in 1811 were 814; but in the two last enumerations they have not been distinguished.

1746. *Cambridgeshire*, besides its scenes of sober industry and high intellectual exertion, displays others of a very different kind, yet equally characteristic of England; for it is at *Newmarket* that *horse-racing* has chosen its most favourite ground. This town lies on the Suffolk border, and within the county of that name, amid bleak hills, that have, however, a sufficient extent of level heath to make the finest course in the kingdom. The amusement, animating in itself, and deriving some elegance from the beauty of the animals engaged in it, might, without blame, be pursued in moderation; but the deep and ruinous betting, and the various forms of dissipation usually attendant on it, render Newmarket one of the most dangerous scenes for young men of fortune. The town itself is small, consisting of one long street, chiefly filled with inns and coffee-houses for the reception of the sporting world, who crowd thither in the appropriate seasons, which are April, July, and October. The bustle is then immense. "Trains of horses," says Dr. Spiker, "were led up and down the streets. Excellent equipages, gigs, curricles, landaus, flew past us and past each other with the swiftness of an arrow. Horses were prancing about with their riders; jockeys were carrying bridles to and fro: in short, all was life and bustle." The course is covered with turf, whence the pursuit of horse-racing itself is usually designated *the turf*. Close to the goal is drawn on rollers a small wooden house, in which sits the *judge*, usually an experienced groom, who decides which is the winner; a delicate task when the difference does not sometimes exceed half a head. The stand is an open raised house for ladies and other merely curious spectators; but men of real business crowd round the betting post, immediately behind the judge, where they remain closely wedged together, "and nothing is heard but the continual cry of twenty, thirty, forty, two hundred pounds on such a horse."

1747. *Of other places*, the small curious city of Ely rises like an island amidst the surrounding fens, and displays a magnificent cathedral. Wisbeach, a neat thriving town on a navigable branch of the Ouse, different from that of Lynn, combines a prosperous trade with some spirit of literary enquiry.

1748. *The small county of Huntingdon* lies to the eastward of Cambridge, by which it is partly enclosed. The two are governed by the same sheriff, chosen alternately in each. Huntingdon is entirely agricultural, but on the north-east side is somewhat encroached upon by the fens; which, however, have been much improved by draining. In other parts the moisture is merely such as to render the pastures peculiarly rich, and adapt it for producing that cheese called Stilton, which seems to rank above any other in Britain. Huntingdon, the county town, though small, has an antique and respectable appearance. St. Ives is a large pleasant village on the Ouse, whose banks are, in this part, hilly and wooded. Stilton claims little notice except from its cheese.

1749. *Lincolnshire is an extensive and important county*, occupying all the eastern coast from the Wash to the Humber. The southern territory, called, from that circumstance, "Holland," comprises more than half of the Bedford level, or fen country, and is naturally an almost continuous swamp; but a great extent of it has now been drained, and produces fine pasture land, and excellent crops of oats. The middle and northern interior is high and somewhat bleak, not very well fitted for grain. The rearing of live stock forms the chief occupation; and Lincoln has breeds of every description that are held in high estimation. The sheep, which are very numerous, amounting, it is said, to upwards of 2,000,000, produce that species of wool called long wool, which, from the length of its staple, is chiefly fitted for worsted, baize, and other fabrics. Rabbits, almost innumerable, are bred in the upper districts; and the unreclaimed fens, during the wet season, swarm with teal, ducks, geese, and aquatic game of every form and description, with which London and many other parts of England are chiefly supplied from this county. Manufactures have entirely deserted it; even its own wool, since the late inventions in machinery, is no longer spun or carded within itself. The internal intercourse is considerable, as the Witham and Axeholme, streams of some importance, flow, respectively, to the Wash and the Humber; while the Trent, during all its course through this county, is navigable for large vessels. Artificial channels unite these streams, particularly the Foss Dyke, between the Witham and the Trent. Foreign commerce, however, is much limited by the increasing sand-banks, by which the coasts and harbours are obstructed.

1750. *The city of Lincoln* was, during the middle ages, one of the most conspicuous and

splendid capitals of England. The cathedral (*fig. 149.*) still holds the very first rank

149

LINCOLN CATHEDRAL.

among religious edifices. From a distance its three towers appear conspicuous; two of them 180, and one 300, feet high, and ornamented with various pillars and tracery; and as the structure stands on a hill, in the midst of a vast surrounding flat, it has the most commanding site in the county. The most embellished part is considered to be the western. When plundered, with devout rapacity, in 1540, by Henry VIII., it was found to contain an extraordinary treasure, not only in gold and silver, but in pearls, diamonds, and other precious stones, gifts of the faithful during many ages. Lincoln having fallen

from its high estate, is supported only by its county trade, and by the remaining opulence of the cathedral; it holds a moderate rank among provincial towns. Its fifty churches are reduced to eleven; and the fragments of the others are dispersed throughout the town, many ordinary houses being adorned with Gothic arches, doorways, and windows.

1751. *Of other towns*, Boston on the Witham, near its junction with the Wash, carries on the trade of Holland, or southern Lincolnshire. After declining from early prosperity, it has considerably revived since the fens have become productive. It now exports the grain, and affords a great market for the cattle reared in them, and has thus doubled its population. A fine Gothic church attests the original prosperity of Boston. Spalding and Holbeach are small towns among the fens. Gainsborough has some trade by the Trent, which is navigable thus far for vessels of 150 tons. Louth, from the interior, sends by a canal corn and wool. Great Grimsby, the chief eastern port, after seeing nearly all its commerce transferred to Hull, has of late somewhat revived. Stamford and Grantham are respectable old towns, a good deal decayed; but the revival of their importance is favoured by their position on the great north road.

SUBJECT. 3. *Central Counties.*

1752. *Under this term we shall comprehend* that part of the interior of England which is bounded on the south and south-west by the two divisions already described; on the north and north-west by Yorkshire and Lancashire; and on the west by the counties of Salop, Worcester, and Gloucester, which will be ranked among the western counties.

1753. *In a description* of this portion of the country, LONDON claims a distinct and separate notice. As the metropolis of the united kingdom, it is the seat of legislation, jurisprudence, and government; the principal residence of the sovereign, at which affairs of state are transacted, and relations maintained with foreign courts; the centre of all important operations whether of commerce or finance, and of correspondence with every quarter of the globe.

1754. *London*, in its comprehensive sense, includes the city and liberties of London, the city of Westminster and its liberties, the borough of Southwark, and the parishes and precincts contiguous to those three component parts of the metropolis. Its extent, from Poplar in the east to Belgrave-square in the west, is nearly eight miles; its breadth, from Islington in the north to Walworth in the south, exceeds five miles. The circumference, allowing for inequalities, is computed at thirty miles. The buildings, streets, squares, and other spaces, including that taken up by the river Thames, winding from the eastern to the western extremity, about seven miles on an average breadth of a quarter of a mile, occupy an area of eighteen square miles.

1755. *By a more convenient topographical arrangement*, London has been divided into six grand portions: 1st, the City, which is the central division; 2d, the western division, including Westminster; 3d, the north-west division, including the district north of Oxford-street and west of Tottenham-court-road, — these two divisions make the west-end of the town; 4th, the northern division, comprising the whole district north of Holborn and the City from Tottenham-court-road on the west to Shoreditch and Kingsland-road on the east, including St. Pancras, Somers-town, Pentonville, Islington, Hoxton, and Kingsland; 5th, the eastern division, including the whole district east of the city and of Shoreditch; 6th, the southern division, comprising the borough of Southwark, and the mass of buildings extending from Rotherhithe to Vauxhall, and ranging southward for more than two miles. The divisions north and south of the Thames communicate by five bridges, — London Bridge, Southwark Bridge, Blackfriars, Waterloo, and Westminster bridges.

1756. *The port of London* extends from London Bridge to Deptford, a distance of about four miles, with an average breadth of from four hundred to five hundred yards. Its divisions are the Upper, Middle, and Lower Pools, and the space between Limehouse and Deptford. Connected with it are certain spacious docks, which will be hereafter noticed.

1757. *The population of London*, according to the returns in 1831 of the census in 1830, is thus stated : —

	Persons.
City of London within the walls	57,695
— without the walls (including the Inns of Court)	67,878
Borough of Southwark	91,501
City of Westminster	202,080
Parishes within the bills of mortality	761,348
Adjacent parishes not within the bills	293,567
Total	1,474,069

1758. *The north division of London*, as viewed from the most central and elevated point, rises gently from the Thames, and extends to the foot of a range of hills on which are situated the villages of Hampstead and Highgate. On the east and west are fertile plains extending at least twenty miles, and watered by the winding and gently flowing Thames. On the south, the distant view is bounded by the high grounds of Richmond, Wimbledon, Epsom, Norwood, and Blackheath, terminating in the horizon by Leith Hill, Boxhill, and the Reigate and Wrotham Hills. Shooter's Hill is a conspicuous object to the eastward; and, in a more northerly direction, parts of Epping Forest and other wooded uplands of Essex.

1759. *London* retains in its name an evidence of its Gothic origin. Its founders were the Trinobantes, by whose name geographers have distinguished it from the more ancient capital of Scania, still designated, in the works printed at its university, *Londinum Gothorum*.^{*} So early as the reign of Nero, London had become a place of considerable traffic, as appears from Tacitus, the earliest of the Roman historians who mention it by name. The Romans fortified it with a wall, and made it one of their principal stations. At the beginning of the third century, in the reign of the emperor Severus, it is represented as a great and wealthy city, and considered to be the metropolis of Britain. Such was the extent of its commerce, that we are told, by the historian Zosimus, that, in the year 359, 800 vessels belonging to this place were employed in the exportation of grain. In the end of the sixth century, it became the capital of the East Saxons, whose king, Sebert, is generally reputed the founder of the cathedral church dedicated to Saint Paul, and of the abbey and abbey church of Westminster. After the union of the seven kingdoms, Egbert, in 833, held here his first *wittenagemote*, or council: but London was not constituted the capital of England until its recovery from the Danes by Alfred, who laid the foundation of its present municipal government. William of Normandy, whose interest it was to conciliate the citizens, though he built the fortress called the Tower, to keep them in awe, confirmed the privileges and immunities which they had enjoyed under his patron Edward the Confessor; subsequent sovereigns augmented and extended them by various charters, one of which, granted by King John, authorised "the barons" of London to choose a mayor annually, or continue the same person in that office from year to year, at their pleasure. The city attained to great splendour under Edward III., who held frequent tournaments in Smithfield and other places; and its architecture at that period exhibited every variety of the richest style of Gothic, both in public and private edifices. The cathedral of St. Paul held the pre-eminence; and its spire is said to have been five hundred and twenty feet high. The streets were mostly narrow, and the higher stories of the houses projected over the lower. There were no glass windows; and on the ground floors the wares of tradesmen were openly displayed. Notwithstanding several visitations of fire and pestilence, London continued to increase, especially after the accession of the Tudors, when the overthrow of feudal vassalage, and the more frequent resort to the capital, caused an augmentation so rapid as to alarm the government. The dissolution of monasteries, of which London contained so large a proportion, accelerated this increase, while it gave an impulse to industry and commerce. In the reign of Elizabeth, the influx of strangers driven from the Netherlands, by the persecutions of the Duke of Alva, heightened the alarm, and the queen was even induced to issue the absurd and futile decree that no more dwelling-houses should be built; a pro-

^{*} Now *Lund*, in Schonen, the southernmost province of Sweden, the seat of a university founded by Charles XI. It is said to have been a flourishing city at the birth of our Saviour, though its present population scarcely exceeds 800. The similarity of the modern names and the *identity* of the Latin appellations are striking.

hibition which does not seem for a moment to have retarded the growth of the city. Her public spirit was more sensibly manifested after Sir Thomas Gresham had erected a bourse for the merchants, which she visited in great state, and caused to be proclaimed "The Royal Exchange." In this reign the luxury of coaches was introduced from Holland, by William Boones, a Dutchman, who was appointed coachman to the queen. It was an epoch alike intellectual and prosperous, adorned with the names of Bacon, Cecil, and Walsingham; of Raleigh and Drake; of Shakspeare, Spenser, and Jonson. Some of these great men also illustrated the pacific reign of James I., scarcely disturbed except by one singular event; the discovery of a conspiracy of fanatic jesuits and papists to blow up the king and both houses of Parliament. In 1636, the refinements of Paris and Madrid were emulated in London by the introduction of hackney coaches and sedan chairs. During the civil wars, the capital participated in the troubles that afflicted the country, and also in the advantages accruing from the famous navigation act passed in 1651, during the interregnum. The citizens, secretly alienated from Cromwell and his council by the execution of the king, hailed with enthusiasm the restoration of Charles II., and adopted with indiscriminate eagerness the change of manners introduced by his court and followers from France.

1760. *The reign of Charles II.* includes the most memorable epoch in the history of London. In 1665, a plague swept away 100,000 persons. In September, 1666, broke out that great and awful fire which destroyed 400 streets, 13,000 houses, 89 churches, including the venerable cathedral of St. Paul, the Guildhall, the Herald's College, the Royal Exchange, and many other structures. For the rebuilding of the city, an admirable plan was presented by Sir Christopher Wren, the architect; but the regard due to private property, and the difficulty of reconciling conflicting interests, allowed it to be but very partially adopted. He rebuilt the cathedral of St. Paul and most of the parish churches in the Grecian style, and the front of Guildhall in the original Gothic, of Portland stone. Instead of wood and plaster, the chief materials of the former city, the new dwelling-houses and the halls of the city companies were built of brick, in the substantial though heavy style then in vogue; with greater regard to convenience than to external display: ornament, however, of a certain kind was not wanting. In the streets occupied by traders, gaudy signs with various devices, in iron and gilded brasswork, hung over every door or projected from every house; the simple distinction of numbering not having been adopted, or perhaps thought of. There were no flagged footpaths; the streets were ill-paved; and as there was no system of drainage by sewers, and no distribution of pure water by pipes, they were in some places far from endurable. The city, however, had gained greatly by the change, though with the sacrifice of many interesting memorials of its ancient state, and of its most glorious times. In 1687, the revocation of the edict of Nantes by Louis XIV. gave to London its colony of silk weavers. The revolution of 1688 was effected without the slightest public commotion in London, except that which ensued on the sudden return of James II. to Whitehall, previously to his final departure from the kingdom. The first years of the reign of William and Mary were signalised by the establishment of the Bank of England, the institution of the funding system, and the introduction of those changes in the operations of commerce by which it was necessarily accompanied.

1761. *Westminster*, though founded in the time of the Saxons, and chosen at an early period as a royal residence, did not at first keep pace with London. The abbey and its church, founded by Sebert, gave place to a grander structure raised by Edward the Confessor; and afterwards enlarged, if not wholly rebuilt, by the accomplished architects who reared so many splendid fabrics of Gothic masonry in the reigns of Henry III. and Edward I. The celebrated hall was built by William Rufus in 1097 and 1098. Having become ruinous in that of Richard II., it underwent a thorough repair, and received the addition of a new roof, and a stately portal at the western entrance. That monarch made it a scene of luxurious banqueting, which provoked the severe but unavailing censures of his uncle, John of Gaunt. In the reign of Elizabeth, Westminster consisted only of a few streets adjoining the hall and the abbey. On the dissolution of monasteries, Henry VIII. converted this religious establishment into a college, appointing William Benson the abbot to be its first dean. He afterwards converted it into a bishopric, assigning all Middlesex except Fulham as its diocese. Westminster thus became a city, and has ever since retained that rank by courtesy, though it never had but one bishop, having been, in 1550, transferred by Edward VI. to the see of Norwich.

1762. *The city of Westminster* is comprised in the united parishes of St. Margaret and St. John; the liberties include seven other parishes, St. Martin's in the Fields, St. James's, St. Ann's, St. Clement Danes, St. Mary's le Strand, St. George's Hanover Square, and St. Paul's Covent Garden, with the precinct of the Savoy and that of St. Martin's le Grand. Several of the parishes westward of Temple Bar had each its church and contiguous village, communicating with each other by roads and footpaths. The Strand was originally a high road connecting London with Westminster by the village of Charing. A range of mansions, among which the Savoy Palace was conspicuous, extended along its south side; a con-

venient site from its proximity to the river, at a time when that was the principal communication with London, Westminster, and the theatres at Bankside, in Southwark. The names of the proprietors of those mansions have been conveyed to the streets since erected there; as Essex, Norfolk, Somerset, Beaufort, Buckingham, Cecil, Craven, and Northumberland. On the north side of the Strand, a considerable extent of ground, formerly belonging to a religious house, became the property of the family of Russell at the Reformation: in the reign of Queen Anne this quarter was the centre of fashion, and was afterwards chosen as the site of the two national theatres, Drury Lane and Covent Garden. After the Restoration, the west end of the town rapidly increased; and its inhabitants, affecting superior refinement of manners, claimed to be considered as a distinct class of beings from the industrious merchants east of Temple Bar. The distinction of court and city was maintained in the comedies of Congreve, Vanbrugh, Farquhar, and their successors, as well as in the periodical essays of Addison and Steele, which so happily illustrated the manners of that age. By degrees, as the vacant ground was built upon, the two cities and their suburbs were united; the fields near St. Martin's and Leicester House were covered with streets; and at length the distant villages of Mary-le-bone and St. Pancras became integral parts of the metropolis. A splendid quarter, now occupied by the most fashionable part of the community, has been built to the west of St. James's Park and the new palace. All the villages surrounding London, formerly at some distance, — on the east, Stepney and Limehouse; on the south, Peckham, Camberwell, Brixton, Clapham; on the west, Brompton and Knightsbridge; on the north, Hackney, Hoxton, Islington, to which we may even add Highgate and Hampstead, — have swelled into large towns, and, being joined to the metropolis by continued ranges of streets, may be considered as integral portions of it. The population within a radius of eight miles from St. Paul's, which is all virtually London, does not fall short of 1,800,000.

1763. *The growth of London*, as a port, was at first by no means rapid. Notwithstanding the impulse given to commerce, after Vasco de Gama and Columbus had navigated to the East and West Indies, and although an East India Company was established so early as 1600, the number of ships then trading to this port was comparatively very small. Indeed, less than a century ago, London had not one twentieth of its present trade. Its subsequent increase has been accelerated by various causes, the operation of which might furnish an interesting subject of enquiry. During the wars with France, from 1793 to 1815, especially while the continental system of Napoleon was in full vigour, London engrossed almost all the foreign trade of the kingdom; which began to return to its wonted channels after the conclusion of peace. In 1824, there entered into the port of London from foreign parts 3132 British, and 1643 foreign shipping; 513 from Ireland; 7117 colliers; 11,213 coasters; 3769 fishing vessels. In 1832, there entered the port of London 2025 ships, of the burthen of 325,299 tons; and 851 foreign, of 150,425 tons. Of these, 415 were from Russia; 5022, the Netherlands; 256, Portugal, &c.; 282, German States; 201, Spain; 305, France; 230, Prussia; 103, Denmark; 105, Italy; 73, United States; 135, foreign America; 20, China. In 1832, besides boats and other craft not registered, there belonged to the port of London 2669 ships, of the burthen of 565,174 tons; manned by 32,786 men and boys. In the same year, the gross customs duty collected in the port of London amounted to 9,434,854*l.*

1764. *The Port of London* has already been described as extending from London Bridge to Deptford, a distance of four miles; the average breadth being fully a quarter of a mile. Even these limits were far from affording adequate accommodation to the shipping; and the example of improvement exhibited by Liverpool at length roused the merchants of London to form companies for constructing docks, with commodious quays and warehouses. The *West India Docks*, stretching across the isthmus forming the Isle of Dogs to the Middlesex side of the river, were opened in 1802. They consisted originally of an import and an export dock, the former containing about 30 and the latter about 25 acres of water, exclusive of basins. To these have recently been added the south dock, formerly the City Canal. The warehouses at the West India Docks are of vast extent, and are, in all respects, most commodious. The *London Docks*, also of very great extent, are situated at Wapping. The tobacco warehouse belonging to them is the largest and finest building of its kind in the world. It covers a space of near 5 acres! The vaults underneath the ground are 18½ acres in extent; and, excluding gangways, &c., have stowage for 66,000 pipes of wine! There are also the *St. Katharine's Docks*, adjoining the Tower; the *East India Docks*, at Blackwall; and the *Commercial Docks*, on the Surrey side of the river. Owing to the competition of the different companies, all sorts of dock charges are now reduced to the lowest level, and hardly one of the concerns can be said to be profitable. The dividend on London Dock stock in 1833 was only 2½ per cent.; and it is supposed that the dividend on the stock of some of the other dock companies will, at no distant period, be even lower.

1765. *Southwark*, the third great portion of the metropolis, (more commonly called the *Borough*, and as such returning two members to parliament,) is situated on the south bank of the Thames. It is considered at least coeval with London, if not more ancient; and

the Romans are said to have raised the large embankment by which it is protected from the river. The Borough was governed by its own bailiffs until the year 1327, when a grant was obtained by which the lord mayor was constituted bailiff and empowered to act by deputy. The inhabitants afterwards recovered their former privileges, and enjoyed them until Edward VI. granted Southwark to the city of London for a sum of money; after which it became one of the city wards by the name of Bridge Ward Without. Southwark is much frequented by agriculturists from Kent, Surrey, and Sussex; and is the principal hop-market in the kingdom. Numerous streets in every direction connect it with the surrounding villages; and by the five magnificent bridges it communicates with every quarter of London and Westminster. Yet, having never been the centre either of commerce or of fashion, it has always held a subordinate rank; and at present the number of inhabitants does not equal a tenth of the entire population of the capital.

1766. *London*, though not the most splendid, is the cleanest, the healthiest, and most commodious metropolis in the world. It is well built, well paved, well lighted and abundantly supplied with water for domestic purposes, and for the all-important object of preventing conflagration. Foreigners who visit it for the first time soon discover that utility, not ornament, is the main characteristic of the town, and that business, not amusement, occupies the minds of its inhabitants. The main streets are spacious; and all the streets have the advantage of flagged foot-pavements on each side. The houses are of brick; and though in the most populous streets discoloured by smoke, have by no means a gloomy appearance. Having been built at various periods, and chiefly on the site of old streets or along the lines of roads, the metropolis can lay no claim to regularity of plan; some parts are regular, others irregular: but it is for that reason more agreeable than if it had been a parallelogram of streets intersecting each other at right angles, than which nothing can be more wearisome to the eye, especially if, as in the new town of Edinburgh, the walls be built, and the streets paved, with stone of the same grey colour, producing an effect which may truly be called dismal. The charm of London, as a great city, is its variety. Those who dislike the high-piled and narrow streets of the city, shady in summer, and sheltered from cold winds in winter, may delight in the spacious streets and squares of the west end of the town: those who desire to contemplate what Dr. Johnson called "the full tide of human existence," may visit Cheapside, Fleet Street, or the Strand: Pall Mall, and St. James's Street, by some fortunate peculiarity of position, not easily defined, look light and cheerful in the heaviest weather; Bond Street is still the resort of gaiety and fashion; and Regent Street, for architectural effect, is the grandest street in Europe. Great improvements have been made on the north side of the Strand from Charing Cross to Burleigh Street, by taking down an immense mass of small and old houses, partly in narrow streets and courts, and erecting others of large dimensions, and forming wide and handsome streets. Here also has been erected the elegant and commodious structure of Hungerford Market. Another improvement is that of opening a line northward from Bridge Street, Blackfriars, through the site of Fleet Market and across Clerkenwell, to Islington: it is intended that a parallel line should extend from Waterloo Bridge across the Strand, past the portico of Covent Garden Theatre, and into the northern district of the metropolis.

1767. *The public buildings of London* would many of them require a great sacrifice of private property to expose them advantageously to view. But here the remark so often made by foreigners again suggests itself, — that business, and not display, occupies the minds of the inhabitants. They want no grand avenue to afford a prospect of St. Paul's, — no range of quays for promenading along the river. Though not utterly indifferent to public walks, they regard even them rather as spectacles, than as places of recreation; and in Hyde

Park all the company in carriages, on horseback, or on foot, are crowded along the eastern line, as if the sole purpose of the many were to see and to be seen. Munificent in contributing to the expense of constructing public edifices, they regard the demolition of property for the purpose of displaying them as mere extravagance.

1768. *St. Paul's Cathedral* (fig. 150.), the masterpiece of Sir Christopher Wren, is allowed to be the finest specimen of

ST. PAUL'S.

modern architecture in the kingdom, and, after St. Peter's at Rome, may rank as the

finest ecclesiastical structure in Christendom. But it is so surrounded with buildings that the beauty of its exterior cannot be appreciated. The style unites grandeur of design with justness of proportion; but being Grecian, it suggests the idea of a pagan temple appropriated for Christian worship rather than that of a temple founded by Christians. That architecture which is called Gothic is essentially more grand and solemn: it dates its origin from the early propagation of the Gospel; implants in all its ground-plans the symbol of

151

WESTMINSTER ABBEY.

the cross; and may be said to have grown with the growth of Christianity. The interior of St. Paul's is too bare of ornament; but the defect is partly supplied by marble monuments, of the merits of which, as works of sculpture, various opinions are entertained.

1769. *Westminster Abbey* (fig. 151.) is a very noble specimen of Gothic architecture. The interior is grand in design and rich in detail, and the interest which it excites is enhanced by the numerous monuments of kings, warriors, statesmen,

philosophers, and poets, which it encloses. The chapel built at the western extremity by Henry VII. in honour of the blessed Virgin, is in the richest style of the later Gothic, and its exterior has been skilfully renovated.

1770. Among the parish churches of the metropolis, that of St. Stephen's, Walbrook, is distinguished for the fine proportions and finished elegance of its interior. The stately portico of St. Martin's, Charing Cross, excites universal admiration; next to which may rank that of the new church of St. Pancras; the steeple of which edifice, constructed on the model of the Temple of the Winds at Athens, has a very airy and pleasing effect. The other public buildings are too numerous to be described, and a bare mention of them would give little satisfaction. The principal inns of court, and their subsidiary inns, are remarkable rather for plainness than magnificence of architecture. The pile called Somerset House (fig.

152

SOMERSET HOUSE.

152.) would have a grand effect if its eastern wing were completed; and this desideratum is partly supplied by the buildings assigned to "King's College, London." The Mansion House attracts the notice of travellers, from its accordance in style of architecture with a palace in Italy. The Banqueting House at Whitehall is a memorial of the fine taste of Inigo Jones; and its ceiling is decorated with

an allegorical painting from the pencil of Rubens, which is still exposed to view, though the apartment has been converted into a chapel. Westminster Hall, of which the portal has been rebuilt in the original style, is reputed the longest hall in Europe unsupported by pillars. It is 276 feet long by 76 broad. Within it, on coronation festivals, 10,000 persons have dined. On its south side are entrances to the new law courts, the King's Bench, Common Pleas, Exchequer, and Chancery, with an additional court for the vice-chancellor. The central door at the upper end opens into a passage leading to both houses of parliament. The House of Peers is a spacious and lofty chamber, decorated with tapestry representing the defeat of the Spanish armada. The subordinate apartments and passages are of recent construction and of a dignified elegance. The House of Commons, originally a chapel dedicated to St. Stephen, retains, perhaps, too much of that character in its front and side galleries, the seats rising on either hand beneath them, and the speaker's chair exactly in the place where a pulpit might have stood. The house was altered and enlarged, to admit the accession of members consequent on the union with Ireland. The Bank of England is a building of great extent, the larger part erected by Sir John Soane. The

Royal Exchange, rebuilt after the great fire, has been recently repaired. The East India

153

THE MONUMENT.

House, in Leadenhall-street, has a handsome portico in front, completed in 1799. The Tower is the most considerable relic of antiquity in the east of the metropolis; it has still an arsenal and a garrison, being the depository of the regalia of the United Kingdom. The Trinity House, and the New Mint, both situated on Tower Hill, are handsome edifices. The apparatus for coining, in the mint, exhibits one of the most ingenious specimens of machinery moved by steam power that has ever been contrived. The new Post Office, in St. Martin's le Grand, near St. Paul's, is a structure highly honourable to the talents and taste of Mr. Robert Smirke. Of the New Palace in St. James's Park the architect is Mr. Nash, to whose boldness of design the public are indebted for the noble range of buildings called Regent-street, from Pall Mall to Portland Place.

1771. The column called *The Monument* (fig. 153.) is one of the most conspicuous ornaments of the metropolis. The pedestal is 42 feet, the shaft of the column 120 feet, the cone at the top with the blazing urn of gilt brass 40 feet, making the total height of the monument 202 feet; which considerably exceeds that of the Trajan and Antonine columns at Rome. It was erected by Sir Christopher Wren, to commemorate the fire of London, in 1666.

1772. *The bridges of London* attract attention by their beauty and utility. Until the year 1740, the only one existing was *London Bridge*, built in the twelfth century, with arches so narrow, unequal, and ill-placed, as to form a sort of breakwater, occasioning a rapid, or fall of the stream, highly dangerous to boats and barges. Its removal having been determined on, the corporation, after considering various plans offered for a new bridge, adopted that proposed by Mr. Rennie, which was accordingly sanctioned by act of parliament. That celebrated architect dying (11th October, 1821) before the work had been begun, the execution of it was entrusted to his son, Sir John Rennie, under whom Messrs. Jolliffe and Banks were employed as building contractors. The government, regarding the undertaking as national, agreed to contribute 200,000*l.*, on condition that the Lords of the Treasury should exercise a joint control over it with the corporation. According to Mr. Rennie's original design, the new bridge was to have been built on the site of the old one, a temporary structure of wood being provided to prevent interruption of traffic; but the corporation, not sufficiently mindful of the expenses attending new approaches, decided it to be 180 feet higher up the stream. Mr. Rennie's estimate for the new bridge was 430,000*l.* with an additional 20,000*l.* for the temporary bridge; and in regard to the structure itself, that sum proves to have been very little exceeded. The change in the site, with the new approaches chosen by the corporation, added 456,000*l.* to the estimate. "But in consequence

154

NEW LONDON BRIDGE.

of the injudicious nature of these approaches," it is observed, in a professional survey, "others had to be substituted, which raised the actual expenditure to nearly 2,000,000*l.* The work was commenced in March, 1824, when the first pile of a coffer-dam was driven. The first stone was laid in June, 1825; and in July, 1831, the structure (fig. 154.) was complete. On the 1st of August in that year, it was opened, in the presence of King William IV., his queen and the royal family, and a vast concourse of spectators. The bridge consists of five semi-

elliptical arches; the centre arch 152 feet span, with a rise above high water-mark of 29 feet 6 inches; the two next the centre arch, 140 feet span, rise 27 feet 6 inches; the two abutment arches, 130 feet span, rise 24 feet 6 inches. The length of the bridge from the extremities of the abutments is 928 feet; within the abutments 782 feet. The roadway is 53 feet between the parapets, being eight feet wider than any other bridge on the Thames. Of this width the footways occupy 9 feet each, and the carriage-way 35 feet.

1773. *Southwark Bridge*, from Queenhithe to Bankside, Southwark, was projected by Mr. John Wyatt; but the work was commenced under the direction of the late Mr. Rennie, in September, 1814. Of its three arches of cast iron, the central one is 240 feet span; the others 210 feet each. The piers and abutments are of stone, the rest of the work iron: this is the most stupendous bridge of these materials in the world.

1774. *Blackfriars Bridge*, built by Mr. Robert Mylne, between the years 1760 and 1769, has 8 piers and 9 elliptical arches; the centre one 100 feet span; those on each side respectively 93, 80, and 70; the length is 995 feet, the breadth of the carriage-way 28 feet, the flagged foot-ways 7 feet each.

1775. *Waterloo Bridge* (fig. 155.), begun in 1811, and completed in 1817, was planned

WATERLOO BRIDGE.

by Mr. George Dodd; but in consequence of a misunderstanding between him and the company, the execution was intrusted to Mr. Rennie. It has nine arches, each 120 feet span; the piers are 20 feet thick. The balustrades are of Aberdeen granite, the other parts of Cornish granite.

1776. *Westminster Bridge*, built between the years 1739 and 1759, has fourteen piers supporting thirteen large and two small arches. The width of the middle arch is 76 feet; that of the two next, 72, that of the last, 52. Of these structures, Waterloo Bridge is entitled to the pre-eminence, and may be regarded as the finest piece of masonry in Europe. The expense exceeded 1,000,000*l.*; and the returns, it is painful to add, have as yet totally disappointed the hopes of the shareholders in this great undertaking. It must always, however, redound to the glory of the English nation, that these immense works, with the exception of London Bridge, have all been accomplished by associations of private individuals.

1777. *The municipal institutions of London* are venerable for their antiquity, and have received from time to time such modifications as were requisite to preserve and improve them. The city is divided into twenty-five wards, the Borough, as Bridge Ward Without, making the twenty-sixth. Each has for its magistrate an alderman chosen for life; and those persons collectively form the Court of Aldermen. The chief magistrate, styled Lord Mayor, is elected annually, and generally in the order of rotation, from the Court of Aldermen, by the great body of freemen called the Livery, in whom was likewise vested the right of electing four members to represent the city in parliament, but this is now shared by all householders paying 10*l.* a year. Previously to 1475, the right of electing the lord mayor belonged to the Common Council, an elective body representing the several wards; but by an act of the council then made, the election of the mayor and two sheriffs was vested in the lord mayor for the time being, the aldermen, the common council, and the master, wardens, and livery of each of the city companies. These public bodies form a sort of parliament, the court of aldermen ranking as peers, that of common council as the commons. On public occasions when a petition to the throne has been proposed, very important questions have been discussed in these assemblies. The military force of the city formerly consisted of the Train Bands; but under an act passed in 1794, two regiments of militia are raised by ballot, each consisting of 2200 men. No troops can enter the city, nor can its own militia depart from it, without permission of the lord mayor. His power is very great; and though his office be elective, his authority does not cease on the demise or abdication of the king, as that of the commission officers does; and in such cases the Lord Mayor of London is said to be the principal officer of the kingdom. There are two sheriffs, one for London and one for Middlesex; but, from a peculiarity originating in the grant of the sheriffwicks, they regularly make but one officer; and therefore, if one of them dies, the office is at an end until a successor to him is chosen, and the courts of Westminster can award no process to the other. The next chief officers in rank are, the Recorder the Chamberlain, and the Common Serjeant.

1778. *The police of the metropolis* has not been brought to a very high degree of efficiency, but is continually undergoing improvements. There are eleven offices: the Mansion House; the Guildhall; Bow Street; Queen Square, Westminster; Marlborough Street; High Street, Mary-le-bone; Hatton Garden; Worship Street; Lambeth Street, in Whitechapel; High Street, Shadwell; Union Street, Southwark; and Wapping New Stairs, for offences connected with the shipping and port. The Bow Street Police Office is wholly under the direction and management of the Secretary of State for the Home Department. All the magistrates belonging to it are in the commission of the peace for the counties of Middlesex, Surrey, Kent, and Essex, this being the chief police office of England. Subject to its authority is that very efficient body of foot and horse patrol by which the roads within ten miles of the metropolis are watched and guarded during a considerable part of the night. In another department of police a most important change has been effected by substituting for the nightly watch appointed by different parishes without concert or co-operation, a CONSTABULARY POLICE FORCE, regularly organised, and subject to officers appointed by the Home Secretary of State. The men are maintained by rates levied on the different parishes, and are on duty night and day, in successive divisions, relieving each other, like gendarmes. Great advantages may result from this system, when it shall have received those improvements which experience may dictate, and when the parish authorities shall be enabled to satisfy themselves as to the characters of the individuals composing this protective force.

1779. *The gaols and prisons of the metropolis* present a subject which, however painful, cannot be passed without notice. The King's Bench prison, in Southwark, is under the particular authority of the Court of King's Bench. The liberties, or *rules*, comprehend an area contiguous to the prison, three miles in circumference, within any part of which debtors may reside on paying certain fees. The Fleet Prison, chiefly for debtors, is situated on the east side of Farringdon Street; its rules were formerly bounded by that street, Fleet Lane, the Old Bailey, and Ludgate Street; but they were enlarged, in 1824, by an order of the Court of Common Pleas. Whitecross-street prison was erected in 1815—1817, for the reception of such debtors as were liable to be confined in the city gaols of Newgate and the Compter.

1780. *Newgate*, now a place of confinement for prisoners before and after trial, has been placed under new regulations, through the efforts of several benevolent persons anxious to render it as effectual a place of reform as a prison can be. Bridewell, Blackfriars, though a prison, is usually ranked among the hospitals. The Middlesex House of Correction, in Coldbath Fields, erected at an expense of 80,000*l.* has long been the terror of delinquents, through the double punishment of incarceration and hard labour. The Penitentiary at Milbank, erected by government at an expense of 500,000*l.*, was destined for the reception of such convicts as might be selected from those sentenced to transportation or to confinement on board the hulks for a certain term of years. They are confined here to hard labour for a shorter term, part of which is remitted if they behave well. Tothill-fields Bridewell is a large pile of building, finished in 1833. A new House of Correction has been erected at Brixton, in Surrey; and there, as well as at Coldbath Fields prison, a treadmill has been erected for the occupation and punishment of prisoners sentenced to hard labour.

1781. *The charitable institutions of London* would require a volume for their description. The term hospital, applied to many of them, however appropriate, seems so general as to be rather vague. Chelsea and Greenwich hospitals are asylums provided by national gratitude to support the aged or infirm who have devoted their best days to the service of their country by land and sea. Under the system of charity ascribed to Edward the Sixth, by which the poor were distinguished into classes, St. Bartholomew's and St. Thomas's hospitals were assigned to the maimed and diseased, Bridewell Hospital to the employment and correction of the idle, and Christ's Hospital to the support and education of the young and helpless. For the cure of diseases, and for the prompt relief of accidental injuries, there are various institutions of the metropolis; such are the London, Middlesex, St. George's and Westminster hospitals; St. Bartholomew's, St. Thomas's, and Guy's are also celebrated as schools of surgery; the hospitals of Bethlehem and St. Luke's are appropriated to insane patients: there are sixteen medical charities for particular purposes, as the Dispensary for Diseases of the Ear, the Ophthalmic Institution, the Small-pox Hospital, the Vaccine Society, the London Truss Society, the Sea-Bathing Society; fourteen lying-in hospitals and charities: among other foundations may be mentioned the schools for the indigent blind, and for the deaf and dumb; the Philanthropic and Humane Societies, the Refuge for the Destitute, the Foundling Hospital, the Magdalen Asylum, and the Female Penitentiary. To the class of charitable foundations belong also the alms-houses of the various city companies. Besides national societies, such as the Caledonian, the Hibernian, and the Welsh, associations have been formed of natives of many English counties; and the benefit societies of various kinds are too numerous to be particularised.

1782. *The most distinguished schools of the metropolis* are, Christ's Hospital, the Charter-house, Westminster, St. Paul's, and Merchant Tailors' schools. Those for the education of the people on the plan of Lancaster and Bell have been mentioned in another part of this work. For the acquisition of the higher branches of knowledge, an important provision has been made in the establishment of the London University, and in that of the institution called King's College, London.

1783. *Of the scientific and literary associations of the metropolis*, the most considerable are the Royal Society; the Society of Antiquaries; the Society for the Encouragement of Arts and Manufactures; the Royal Institution for facilitating the introduction of useful Inventions and Improvements; the London, and the Russel Institutions. The College of Physicians, and the Royal College of Surgeons, decide on the admission of members to practise in each of those professions. For the cultivation of sciences connected with them, four eminent societies exist, and lectures are established at various theatres of anatomy and hospitals. Of institutions for particular branches of knowledge, the more eminent are the Linnean, the Geological, the Horticultural, the Geographical, and the Zoological societies. As a national repository of literature, of antiquities, and of objects belonging to natural history, the British Museum, elsewhere described, is daily rising in public estimation.

1784. *London is the principal literary emporium of the kingdom.* Almost all books of importance are there printed and published; and thence distributed over the kingdom, forming a considerable branch of commerce. The annual value sold is estimated at from 1,000,000*l.* to 2,000,000*l.* sterling. Being also the centre of intelligence relative to public affairs at home and abroad, the metropolis gives circulation to a prodigious number of newspapers and periodical journals. Some of the newspapers circulate upwards of 8000 a day; and by the profit derived from such extensive sale, and from advertisements, they are enabled to maintain complete and costly establishments for obtaining early political intelligence, and for reporting trials and parliamentary proceedings. The number of single papers published annually in London, as calculated from the stamp returns, exceeds 16,000,000. The metropolis is also the chief market for collections of rare and curious books; and these literary treasures, that have been accumulating since the invention of printing, present a fund of interesting research and speculation, which cannot be paralleled in any other European capital.

1785. *In London, also, the English school of art* may be considered as established; and it is here that the most eminent professors of painting, sculpture, and architecture fix their permanent abode. In all that concerns the drama, the sanction of a London audience is decisive both as to authors and actors; and the same remark may apply with respect to music, both vocal and instrumental. It is a subject of regret, however, that the profits of opera and concert should be chiefly appropriated by foreign professors, to the great discouragement of native talent.

1786. *The manufactures of the metropolis* are too miscellaneous to be particularised; indeed, London may be called a commercial rather than a manufacturing city. The most considerable is the Spitalfields silk manufacture, which, however, has for years remained stationary, while that of other parts of the kingdom has been rapidly extending. In household furniture, especially cabinet-work, the artisans of London take the lead both in the design or fashion of the articles, and in the excellence of their construction. The same may be said of coaches, carriages, and harness, and of watches, of gold and silver plate, and of jewellery. Of articles of consumption, the peculiar product of London is *porter*. In 1823-4, the quantity brewed was 1,168,000 barrels, including a comparatively small quantity of ale; and almost the whole of which was produced by eleven great establishments. The distilleries of British spirits, fewer in number by one half than the breweries, are very extensive, and are conducted with great skill. The consumption of gin has latterly increased; but not nearly to the extent that is commonly supposed. The abolition of the duties on beer and porter will probably, indeed, throw the balance in favour of the latter.

1787. *The foreign trade of London* has, since the peace, continued nearly stationary. The vicinity of Liverpool to the manufacturing districts, and her more easy and frequent intercourse with Ireland, give her considerable advantages. But, on the other hand, the vast population of London and of the basin of the Thames, her proximity to the Continent, the immense wealth and connections of her merchants, will most probably suffice to ensure her predominance. The charges on vessels frequenting the Thames, though within these few years very heavy, are now extremely moderate.

1788. *The inland trade of London* is very extensive, as appears from the number of coaches, waggons, and other vehicles continually arriving and departing by all the great roads of the metropolis, and by the Regent's Canal, extending from the Thames at Limehouse, along the northern boundary of London, to the basin at Paddington, a sort of internal port, communicating with the principal canals of the kingdom. For the correspondence required by commercial and general intercourse, sixty-four mail-coaches and a great number of steam-packets maintain a constant communication between the London General Post-Office and the principal cities, towns, and out-ports, and through numerous ramifications with every town and village in Great Britain and Ireland. The regulated speed of the mails is eight miles an hour, including stoppages; and by the improved state of the roads, a day has been saved in the interchange of letters between London and Liverpool, as well as all towns within the distance of 200 miles from the metropolis. The post-office is the most systematic and economical of all the government establishments.

1789. *London is the great money market of the empire*; much of the correspondence carried on through the post being that of country banks with London bankers, and of private individuals with their agents for the purchase and sale of government securities. The Bank of England, founded in 1694, has become the greatest bank of circulation and deposit in this country and in Europe. Its pecuniary transactions are immense. Its usual issue amounts to about 20,000,000*l.* sterling; it advances about 10,000,000*l.* sterling to government, and discounts bills to the value of about 3,000,000*l.* Though some of its exclusive privileges are curtailed by the late act, this is compensated by the regulation which makes its notes a legal tender. The Stock Exchange, in Capel Court, near the Bank, is the place where purchases and sales are effected by brokers, at a commission of one eighth per cent. on the amount of stock purchased or sold. The establishment consists of a certain number of brokers, about thirteen hundred, elected annually by ballot, and bound in a certain sum to the observance of certain regulations, which are superintended and enforced by a committee. None but members are admitted on the stock exchange; and no stock-broker can, by the regulations, become a dealer, and subject himself to the operation of the bankrupt laws. If he becomes a bankrupt, he is designated a scrivener. The property bought and sold in this market, between the hours of ten and four, is sometimes enormous. London is also the principal emporium in the world for the insurance of ships, merchandise, and property of every description. The Insurance Companies are about twenty in number, of which only three are incorporated by charter. Of other joint-stock companies, for purposes immediately connected with London, the principal are the Water and Gas Light Companies.

1790. *As the seat of legislation and jurisprudence*, London is necessarily the resort of the principal persons in the kingdom during the session of parliament, which usually continues from Christmas to midsummer; and as that period includes three of the four law terms, the afflux of strangers is increased by those who are interested in any proceedings before the courts. It is natural that persons of opulence and leisure should choose to reside in the metropolis during such a period; but, notwithstanding the trite ridicule on a London winter as extending to midsummer, what is called the fashionable season really appears to be regulated not by caprice but by necessity.

1791. *The town mansions* of the nobility and gentry are not so remarkable as their country residences for architectural beauty. Some of them are celebrated for their treasures of literature or art, as that of Earl Spencer for the finest private library in the kingdom, those of the Duke of Sutherland, Marquis of Westminster, and H. T. Hope, Esq. for their magnificent collections of paintings, and that of the Marquis of Lansdowne for some exquisite specimens of antique and modern sculpture. The house and museum of Sir John Soane, in Lincoln's Inn Fields, contains an interesting collection of works of arts and virtù.

1792. *From its rapid increase of late years*, London, in the opinion of some persons, is likely very soon to be overgrown. Yet such an alarm will surely appear unfounded, when we consider that the principal squares exhibit, in the flourishing plantations that adorn them, an agreeable mixture of town and country not to be paralleled in any other capital; that the grounds of St. James's Park, Hyde Park, and Kensington Gardens, emphatically called the lungs of London, are and will be preserved from encroachment; and that the finely disposed enclosure of the Regent's Park is destined in perpetuity for the recreation of the public.

1793. *Middlesex*, with one exception, the smallest county in England, may be regarded as the dairy and garden of London. Its soil is mostly a poor gravel; but, by the copious application of manure, it is fitted for kitchen gardens to the extent of nearly three thousand acres; and from the ready market, yielding a produce of 200*l.* per acre, the same extent of fruit gardens to the west, and about half that extent of nurseries, whence the greater part of England is supplied with choice plants and exotics. But the largest portion of Middlesex is in grass, partly for the support of 10,000 cows, which supply London with milk, which is, in some cases, diluted, and retailed at a great profit; and partly for furnishing its numerous stables with hay, that of Middlesex being said to be made in a superior manner to any other in the kingdom. Great profits have been derived from that species of clay which is convertible into brick. Large tracts have yielded 4000*l.* an acre; and after this clayey substance has been pared off, the soil has been easily restored, by manure, to the uses of agriculture.

1794. *Middlesex is not remarkable for seats of the nobility*; but it contains Hampton Court (*fig. 156.*), built by Cardinal Wolsey, and enlarged by Sir Christopher Wren, and forming one of the largest of the English palaces. Here are displayed many fine and curious pictures, among which are seven of the cartoons of Raphael, regarded as the master-pieces of that renowned painter. They are shown to the public, though not, perhaps, with that full freedom which visitants of taste would desire. The gardens of this palace are formally disposed; but they harmonise with the style of the edifice. Bushy Park, the seat of William IV. while Duke of Clarence, is surrounded with magnificent woods. Chiswick, the highly ornamented villa of the Duke of Devonshire, and Osterley Park, are both in this vicinity, and contain fine paintings. Syon House is the seat of the Duke of Northumberland. But the chief ornaments of Middlesex are its villas, wholly composed of the embellished

HAMPTON COURT.

retirements of the wealthy citizens of London. At Twickenham, indeed, barbarous hands have demolished Pope's villa; but the stranger may still wander on the ornamented grounds, sloping down to the river, on which the eye of the poet was accustomed to rest. Strawberry Hill is a light fantastic fabric, built by Horace Walpole. The villas which cover the sister hills of Hampstead and Highgate command beautiful prospects.

1795. *The other midland counties*, if we except the outer border formed by those of Warwick, Stafford, Derby, and Nottingham, which have each a marked distinctive character, so much resemble each other, that they may be considered in close connection. These counties are, *Hertford, Bedford, Buckingham, Oxford, Northampton, Leicester.* This great inland tract consists generally of a vast plain, not of the same wide exposed flats as in the eastern counties; but varied by gentle undulations, which, in a region of bolder features, could not aspire to the name of hills. The surface is not subject to swamp or inundation; the air is healthy and pure; the agriculturists are of the old steady English character, careful and laborious, but without that great activity and inventive spirit usually excited among farmers who have greater difficulties to struggle with. One exception must, indeed, be made, in the breed of horses and black cattle, to which the annual shows once held at Woburn Abbey gave a great impulse, and which Mr. Bakewell of Leicestershire carried to such perfection as to make the breed of that county famous throughout the kingdom. The whole tract is almost destitute of manufactures. Bedford and Berks have some fabrics of shawls, straw hats, and bone lace, but scarcely amounting to a national object. Silk and woollen hosiery have found their way into Leicester and Oxford shires, and Coventry has for centuries been renowned for its silk manufacture. There are in this district several respectable and ancient towns; but few can aspire to rank with or rival the large manufacturing towns of the north.

1796. *Oxford* justly claims the first rank among the midland cities. Its university, the most richly endowed in Europe, and the nursery of so many great men; the numerous

and extensive edifices connected with it, arranged in such a manner as to produce a truly noble effect, render it one of the most interesting places in England. The visiter, as he passes along either of the two main streets (*fig. 157.*), beholds at every step some antique and majestic structure; he

HIGH STREET, OXFORD.

feels as if he belonged to another and a greater age. Even the houses of private individuals, though not perhaps in strict harmony with the rest, presenting the aspect of ornamented cottages rising one above the other, have a better effect than the usual common-place and mechanical lines of street. This beautiful city is supported almost entirely by the university, which is of great antiquity, having been founded by Alfred, and the principal

buildings which now ornament it built between the times of Henry VI. and Elizabeth. Oxford, in the reign of Charles I., was a place of considerable political importance; parliaments were summoned to meet there, and the king maintained it long as his last strong-hold. At present it is solely distinguished as the tranquil seat of the muses. It has nineteen colleges and four halls, in which reside above three thousand persons, of whom about a third are maintained out of the funds of the colleges; and many, under the character of masters, fellows, and other functionaries, enjoy liberal incomes. Oxford, like Cambridge, improves its students rather by private tutorship, with strict and impartial public examination, than by lectureships; for though these are numerous on the foundation, they have fallen into desuetude, with the exception of a few, which have of late been revived with success.

1797. *Oxford is richly endowed: it possesses the Bodleian Library*, which was the most extensive in England, till that of the British Museum was increased by the library of his majesty George III. It was founded by the bequest of Sir Thomas Bodley, and enriched by subsequent donations, particularly that made by Mr. Gough of his immense collection of British topography. It has also a right to claim a copy of every new book entered at Stationers' Hall. The volumes are commodiously contained in a spacious apartment, and, as our experience can testify, the freest admission and most liberal aid are afforded to the literary enquirer. In the spacious quadrangle which contains this library are also the public schools; a large gallery of portraits having reference to the university; the Arundel marbles, well classed and arranged; and the Pomfret statues, which, though much mutilated, present some fine specimens of ancient sculpture. The Radcliffe Library is a lofty and noble rotunda, the finest library room in Oxford; but it labours under a deficiency of books.

1798. *In respect to striking single objects*, we have already observed that Oxford has not quite so many as Cambridge. Christ-church, however, is an ample and venerable edifice, adorned with some fine old painted glass. In an adjoining apartment is the collection of pictures bequeathed by General Guise, which, though of unequal merit, contains some specimens of unquestioned excellence. New College chapel attracts admiration by its fine series of paintings on glass, executed by Jervis, after the designs of Sir Joshua Reynolds. All-Souls College, likewise Magdalen College, and Queen's College (of recent erection), display architectural beauties of no common order.

1799. *Among the other towns of this extensive district*, Woodstock has a gay aspect, and really interesting features in English history and romance, to which it adds the solid benefit of a large manufacture of leather gloves. Buckingham, Stony Stratford, Towcester, and Daventry are small antique towns, the last three chiefly supported by their situation on the high road from London to the north-west of England. The streets of Stony Stratford have a very bad reputation for their rugged and dangerous character, which the utmost endeavours of the parliamentary commissioners have not thoroughly cured. Newport Pagnell, in Bucks, forms a sort of centre of the lace trade. Bedford carries on some manufactures of this description; and being situated in a rich valley, watered by the Ouse, has a considerable stir in transmitting its produce. The smaller towns of Woburn, Ampthill, and Luton depend chiefly on the fine seats adjoining to them; but the industry of Dunstable is at once attested by the straw hats which bear its name. Hertford is a small provincial capital, now chiefly remarkable for the college which the East India Company have founded, on a very liberal scale, for the education of the civil servants whom they send abroad; but St. Alban's is a town venerable for its antiquity, containing a cathedral of early renown, and ornamented during successive ages. Northampton, a place of considerable name in English history, is still a well-built town on the Nen, with a market-place which has been reckoned the finest in the kingdom. It has a manufactory of boots and shoes for exportation, and of lace. It is a great centre of the inland travelling between London and the north; and the trade in horses has always been carried on in great fairs at this place. Leicester is a still more important provincial capital. It is a place of note in English history, and attests its ancient importance by some fine old churches; but it had fallen into considerable decay, till it was revived by the prosperity of the surrounding country, chiefly in consequence of the introduction of new breeds of stock into fine pastures. This was mainly the work of Mr. Bakewell, who changed the large-boned, disgustingly fat, and coarse-woolled sheep, for a breed displaying the

opposite of all these bad qualities. The horses and hogs of Leicestershire have also a high reputation; and great quantities of the best cheese are brought to its markets. The city of Leicester has also a large fabric of woollen stockings, in which it is only excelled by Nottingham, and which, under favourable circumstances, employs seven or eight thousand persons. Oakham, the capital of Rutlandshire, is a very small town; Rockingham still smaller, but having contiguous to it the remains of a very strong castle, erected by William the Conqueror.

1800. *The seats in this extensive district*, though not so thickly planted as in the southern, are yet numerous, and several may aspire to the rank of palaces. Foremost stands Blenheim, (*fig. 158.*) that proud monu-

158

BLENHIM.

ment of a nation's gratitude to its long unrivalled hero. Yet, though no cost was spared, taste criticises the edifice, in its external aspect, as displaying that minuteness of detail and general heaviness, which characterise the designs of Vanbrugh, the fashionable architect of that age. Some of the apartments, however, are of almost unequalled grandeur; particularly the great hall, fifty-three feet by forty-four, and sixty high, (though Mr. Young thinks this altitude somewhat disproportioned); and the library, one hundred and eighty feet by forty-three. The woods, also, the lake, and the general disposition of the grounds, are greatly admired. The gallery of pictures is one of the very

finest in the kingdom, containing some of the best works of Rubens, Vandyke, and Titian. Stowe, the seat of the Duke of Buckingham, is celebrated as the most elaborate and splendid example of the species of gardening called classical; in which the trim alleys, clipped hedges, and trees fantastically cut into the forms of men and animals were abandoned, and an attempt was made to present nature herself in an ornamented form. Her own proper ornaments, of wood, water, hill and plain, are heightened by the introduction of temples, ruins, statues, inscriptions, and other objects calculated to excite lofty and poetical ideas. A more refined modern taste has rejected many of these accessories, as breaking in upon the idea of simple nature, to which it seeks to make the nearest possible approach; yet, a space of four hundred acres, filled with groves, temples, and meandering streams, must present many beautiful sites. "The rich landscapes," says Walpole, "occasioned by the multiplicity of temples and obelisks, and various pictures that present themselves as we shift our situation; occasion surprise and pleasure, sometimes recalling Albano's landscapes to our mind, and oftener to our fancy the idolatrous and luxurious vales of Daphne and Tempe." The house also is handsome and richly ornamented, and contains some fine paintings. Woburn Abbey, where the house of Russel, by princely shows and festivals, have thrown a new lustre on British agriculture, is a magnificent edifice. The stables, experimental farm, and other appendages of the most useful of arts, excite the admiration of every farmer and even amateur; nor is this residence deficient in the lighter embellishments of painting and statuary. Althorp, near Northampton, where the black-letter sages held their festival, is adorned with many rare and valuable works of art; but it is in London chiefly that Earl Spencer keeps his library, the first in the kingdom. Opposite to Stamford is Burleigh, a noble old residence of Cecil, Elizabeth's minister. It contains a fine library of books and manuscripts; and the Exeter family have enriched it with a collection of paintings, generally supposed to be the most extensive in England. They are chiefly of the Italian school, and illustrate the beauties of its greatest masters; and if too many are by artists of a modern and even secondary class, even these, being fine specimens, are not without their value. Twelve miles west, near Oakham, is another Burleigh *on the hill*, a Doric mansion, one of the finest in England, and once the seat of the gay revels of Buckingham. It has a noble terrace in front, and contains a good library, with some curious paintings. At Ampthill Park, the collection of portraits is interesting. In Hertfordshire, Cashiobury Park, and Nuneham Wimpole are fine seats, well adorned with works of art; and the same may be said of Luton Hoo, in Bedfordshire. On the border of Leicestershire, and half claimed by Lincolnshire, stands the Duke of Rutland's proud castellated edifice of Belvoir. From a lofty height, it overlooks a vast extent of country, including the vale of the same name, one of the richest and most beautiful in England. The collection of paintings, made chiefly by a late duke, is of great value, including a series of the Seven Sacraments by Poussin.

1801. *Four counties, those of Warwick, Stafford, Derby, and Nottingham*, border on the north this great midland region; but all these possess striking and peculiar features, which will require a special notice.

1802. *Warwick* is a noble county. Its woodlands, the remains of the wide ancient forest of Arden, are still extensive, and a great part lies in fine natural grass. The extensive plains are so diversified by hills and rivers as to improve the picturesque aspect of the country, and harmonise with the grand objects of art which it contains. Pasturage predominates greatly over agriculture, occupying nearly two thirds.

1803. *Of the towns*, the first in rank is *Warwick*, ancient and well built, and still preserving a portion of its prosperity by the manufacture of woollens. It has some good buildings ancient and modern; and its chief ornament is the castle, of which a description will elsewhere be found. Of much greater importance is *Coventry*, a large old town, built very irregularly without rule or line, and many of the houses exhibiting the uncouth architecture of a distant period. Its ecclesiastical monuments, however, are of importance. Of the three churches, Trinity, St. John's, and St. Michael's, the last, the only one which displays much beauty, is a very light and elegant structure. At some points, however, where all the three are seen, forming a continuous line of vast extent, the effect is extremely grand. The spire rises to three hundred feet; a perpendicular height which is almost sublime. Coventry has not slumbered on its antique distinctions. The fabric of silk, introduced more than a century ago by the French refugees, has made most rapid progress, so that in 1819 it employed 2819 looms. In the making of watches, also, this city now rivals London. *Leamington*, though its spa is mentioned by Camden, never became a scene of crowded resort, till the beginning of this century; yet so great since that period has been its attraction, that it has risen from a mere village to be a flourishing place. There are both hot and cold baths; and the waters are used either for drinking or bathing. Leamington now possesses, on a handsome scale, baths, inns, a theatre, an assembly-room, — all the accommodation for the sick and the gay. *Stratford* is a considerable town on the Avon, to which the deathless muse has given a name that may proudly vie with any other in England. It is the undoubted birthplace of Shakspeare, the unrivalled master of the English drama. Many things are shown as memorials of the bard, which the severe antiquary may suspect as apocryphal; but the poetical pilgrim is sure that he beholds the genuine tomb of the poet, and the site of the house chosen by him for his final residence; though the house itself a barbarous hand has demolished. He sees the early scenery on which the eye of Shakspeare dwelt, and which without any bold features presents an agreeable variety; while the vicinity of the castles of Warwick and Kenilworth, displaying feudal life in all its grandeur, must have wonderfully opened the mind of the youthful bard. Birmingham is in Warwickshire, according to the record; but as its actual position is clearly that of the capital of the iron country, which is almost wholly in Staffordshire, we propose, though against law and statute, to class it with the great towns devoted to the working of that material.

1804. *There are two castellated seats* in this county, Kenilworth and Warwick, both of

almost matchless grandeur; but the former presents only the picturesque and antique remains of its pristine state (*fig. 159.*). Founded in the reign of Henry I., it was chiefly

159

KENILWORTH CASTLE.

extended and adorned by John of Gaunt; and remained with the princes of the house of Lancaster till wrested from them by the triumph of the house of York. It continued thenceforth a royal appanage; and was bestowed by Elizabeth on her handsome favourite, Leicester, whose residence here, and the splendid fêtes and romantic incidents connected with it, have been so happily worked up by the greatest romance writer of the age. At the close of the civil wars, it was given up wholly by Cromwell to his soldiers for plunder; a destination consummated with such eagerness, and so combined with that love of wanton destruction in which vulgar minds delight, that Kenilworth was reduced to the totally fallen state in which it now appears. The walls are indeed entire, but completely naked, and every where roofless; and the visiter who stands at the interior foot of the tower can trace only by chimneys, and other slight marks, the successive apartments rising above each other till they are terminated by the dome of the sky. Seated on an eminence, and exhibiting in solemn profusion mouldering walls, dismantled towers, shattered staircases, and broken battlements; the endless apartments, the grandeur of some, the studied concealment of others,—the wilderness of galleries,—staircases in every direction,—cells built in the solid wall,—dungeons impervious to the light of day,—caverns and confessionals,—ramparts, turrets, and buttresses,—cause it to exhibit traces of all that is most magnificent, as well as awful and mysterious, in the castles of the feudal age. This stupendous pile is now abandoned to total neglect; and when the present writer visited it, hogs were wallowing in the mire, in the court of this once almost regal seat of Lancaster and Dudley. Kenilworth exhibits the feudal age in its total downfall; but the traveller has only to proceed a few miles in order to see it entire and in full glory. This is in the proud mansion once inhabited by the king-making Earl of Warwick (*fig. 160.*). In the reign of Edward the Confessor, this castle

160

WARWICK CASTLE.

was a fortress of the crown; but having been demolished in the course of civil contests, its present existence is due to Thomas Beauchamp, Earl of Warwick, who, in the fourteenth century, distinguished himself at the battles of Cressy and Poitiers. It remained in the hands of that powerful house till the reign of Edward IV., who seized an opportunity of annexing it to the crown. It was afterwards bestowed by King James on Lord Brooke, who spent a large sum in restoring it from a state of decay; and when it had again suffered from time, Francis, the late earl, repaired it so judiciously, and made even his additions in such harmony with the original pile, that he may be considered almost the creator of the edifice in its present state. It is scarcely possible to give to those who have not seen it an idea of this range of mighty clustering towers, their walls richly mantled with ivy, and overlooking a perpendicular rock which rises from the Avon; while vast woods embosom it on every other side. The entrance, cut through a rock, and opening at once on three of the loftiest towers, has an effect truly striking. The interior is equally grand and interesting. First is a passage or corridor upwards of 300 feet in extent, seen from end to end, and along which the state apartments are arranged. The grand hall, 62 feet long, is wainscotted with oak, hung with armour, and maintained in full feudal keeping. There are many fine pictures; but, perhaps, the best productions of the mimic art scarcely produce their due impression, on first view at least, in the presence of such mighty realities of nature and art.

1805. *Staffordshire* has a somewhat bleak and uninviting aspect. A great part of its eastern surface is composed of moorland hills, some of them above a thousand feet high,

and affording only scanty pasturage; yet, as these hills give rise to the Trent, and to numerous smaller rivers which feed the great canals, they are highly serviceable to British inland commerce. Of the cultivated part of the county, the greater part is arable, though there are rich pastures along the rivers; but, on the whole, the farms are smaller, and improvements less advanced, than in the other midland counties. Other sources of wealth, opened within the last fifty years, appear to have, in a great measure, absorbed attention: its mineral stores are immense. The region of coal is supposed to be about 50,000 acres in extent, and cannot be exhausted for ages. Besides its economical uses, this mineral is the main basis of the works and manufactures of the county, and of all those in the north-west of England, which, but for this ample supply of fuel, could never have attained their present astonishing height. Iron, the most useful of metals, exists in equal abundance; and since the discovery that it could be worked with coke, iron works have been established on an immense scale. The whole district from Wolverhampton to Birmingham may be called a Cyclopean land, where furnaces without number are continually pouring out fire and smoke. Even in the darkest night, the flames are visible in the distance, and the horizon appears in a glow. Staffordshire is also traversed by limestone rocks, some of which approach to the quality of marble. The clays are more valuable, as they afford the material of the pottery, which forms the other great Staffordshire manufacture. It is long since some coarse vessels were made at Burslem; where, in the course of last century, some improvements in the art of pottery were made. But it was Mr. Wedgwood who, by a series of happy inventions, raised this fabric at once to the highest perfection, and rendered it an object of national importance. Not content with the native materials, he imported the finest white clays and best flints from the southern counties; and formed that variety of articles called Wedgwood's ware, applicable to all purposes of use and ornament, and superior in some respects to the best porcelain. Hence has sprung up a range of villages forming a district called the Potteries, of which Burslem is the centre, and which contain about 60,000 inhabitants.

1806. *The principal cluster of large towns in Staffordshire* consists of those in the southern quarter which are employed in making iron, and manufacturing it into various forms. Of this district Birmingham is undoubtedly the capital; and we therefore reserve for this place the description of that great emporium of British industry.

1807. *Birmingham* is named in history so early as the reign of Alfred; and at the remotest periods iron is mentioned as its staple. In the time of the civil wars, it naturally took part with the parliament against the king; and was besieged and taken by Prince Rupert. The Restoration, though not a welcome event to Birmingham, gave a beginning to her prosperity, by the market which it afforded to the toys and ornamental articles for which it became more and more noted. But the grand impulse given was early in the last century, when John Taylor Esq., the founder of the wealthy family of that name, Matthew Boulton Esq., and other individuals, by the magnificence and spirit of their undertakings, and by their liberal patronage of skill and ingenuity in every line, contributed greatly to the establishment of the manufacturing fame of the town. Mr. Boulton, having secured the celebrated Mr. Watt, established, in conjunction with him, at Soho, near Birmingham, their immense manufactory, in which talent, science, capital, experience, united every thing which could raise hardware articles to perfection. Pre-eminent above all is the steam-engine, which Mr. Watt, its great improver, not only applied to the use of his works here, but constructed for the rest of England. The copper coinage executed at Soho by steam power for the use of government has been greatly admired. Under the impulse of such an example, the citizens of Birmingham soon produced their standard articles of a cheapness and excellence which defied all competition.

The articles manufactured in Birmingham consist, in a great measure, of such as, individually, appear unworthy of being named, yet astonish and dazzle by their magnitude, when half the world is to be supplied with them; such as pins, buttons, nails, paper trays, filigree, and toys. The buckle manufacture, now almost extinct, was the source of employment to many hundreds during the latter half of the century. There are not wanting, however, fabrics of greater magnitude, taken even singly, such as that of fire-arms, &c. During the last war, the gunsmiths of Birmingham met the demand with such energy, that, on one occasion, they delivered to government 14,000 muskets in a week. Of ponderous machinery, none, perhaps, is more interesting than that of the metal rolling-mills. Birmingham, at least that largest part which is new, is fairly and commodiously built, with suitable churches and other edifices, but without any thing prominent in architecture, or any antique monuments. The town can boast of enlightened citizens, under whose auspices letters and the arts have been cultivated with ardour. The institutions for the education of the poor are not, perhaps, surpassed by any in the kingdom for extent and efficacy. Like all other great seats of manufacture, the place has suffered deeply by the changes from war to peace, and by the many recent vicissitudes; yet the conduct of its citizens has been generally good.

1808. *The other great manufacturing towns*, almost all in Staffordshire, are, *Wolverhampton*, a very populous place, of considerable antiquity, with a very fine old church; but indebted for its present greatness to the making of locks and keys in a manner superior to any town in the world. *Wednesbury* must be still more ancient, if it derives its name from Woden: it has a very fine old Gothic church; but its main boast at present is, the making all the hard materials of coach harness in an unrivalled manner. *Walsall* flourishes by the making of every thing connected with saddlery; *Dudley* by its nails: but it has also a castle of some note in history, commanding a view of seven counties, and seated on vast excavated limestone rocks. *Bilston*, in the very centre of the coal and iron mines, is busily employed in the exportation of their produce.

1809. *The nominal capital, Stafford*, is yet to be noticed; an ancient but small town, of neat appearance, ornamented with the usual county buildings. The Grand Trunk Canal, however, passing by it, has given an

impulse to its industry ; and it carries on a considerable manufacture of boots and shoes. Newcastle-under-Lyne, and Tamworth, are both considerable towns on one of the great London roads.

1810. *Lichfield* is a more elegant and interesting place. Its most prominent object is the cathedral, of high antiquity, the finest part of which was built in 1140, by Roger Clinton ; some particular portions have been pronounced equal to any thing of the kind in Britain, or even in Europe : such are the portico, richly adorned with sculpture ; the choir ; and St. Mary's chapel. It contains also the monuments of eminent characters belonging to Lichfield. The society fixed there by this richly endowed establishment, together with the neatness of the town, and its pleasant situation, have induced many of the gentry in this quarter to make it their residence. These circumstances may have contributed to give to Lichfield that intellectual character which is so conspicuous, and has made it almost the literary metropolis of south-western England. The birth and early education of Johnson and Garrick are alone sufficient to immortalise it. More recently, Miss Seward and her friends have zealously cultivated letters and poetry ; and Dr. Darwin may, perhaps, be considered as a member of the same school. Lichfield enjoys high privileges as a city, having a district of some extent round it considered a county of itself. It has some small manufactures of sheeting and sail-cloth.

1811. *Seats* are not particularly numerous in Staffordshire. Trentham Park is a noble mansion of the Marquess of Stafford, where the family portraits are preserved. Leighton Beau Desert, the seat of the Marquess of Anglesey. Etruria, erected by Mr. Wedgwood, has been rendered classic and splendid, even amid the smoke of the surrounding manufactures.

1812. *Derbyshire*, in its natural features, is perhaps the most remarkable of any county of England. Except in the lower and southern districts on the Trent, the whole county is traversed by ranges of rugged and rocky hills, penetrated by vast excavations, and separated by narrow valleys. In these bleak and high districts, an inferior agriculture is necessarily practised. Oats are the chief grain ; and the sheep and cattle are often diminutive. Lead is abundant and characteristic, occurring chiefly in the form of galena, with a very small admixture of silver. Iron is also worked very plentifully. This county is also celebrated for the variety and beauty of its calcareous substances, particularly the kind called Blue John (fluor spar), which, by the skilful application of a gentle heat, is made to exhibit the most brilliant colours. Lastly, there are numerous hot springs variously impregnated ; and the county contains two of the most remarkable watering-places in the kingdom, Matlock and Buxton.

1813. *The scenery and the wonders of Derbyshire* have attracted much attention. The north-eastern quarter, in particular, called the "High Peak," exhibits an aspect altogether peculiar. In proceeding to Castleton, the traveller passes through the Winyats, or gates of the winds, a narrow road of about a mile in length, between precipices a thousand feet high, dark, rugged, and perpendicular. At the end of this road opens on one side Mam Tor, or the Shivering Mountain, 1300 feet high, shattered, and precipitous ; on the other the High Peak itself crowned with the ruins of a Saxon fortress ; and at its foot, the

wonder of wonders "the Peak Cavern" (*fig. 161.*). This is a huge gulf, 42 ft. high and 120 long, at the foot of perpendicular cliffs of amazing height. Gilpin considers it as the only cavern which can be called sublime, most others resembling mere holes. The visiter is thence guided through a succession of dark cavernous apartments, and is ferried along a subterraneous river ; above which the rocks rise so close, that he must lie flat on his face. At the end of somewhat above 2000 feet the cavern terminates, or, at least, becomes no longer passable. Elden Hole is an object of a still more awful character. It is a fissure near Buxton, which descends perpendicularly to an

PEAK CAVERN, DERBYSHIRE.

unknown depth. A line of 2652 feet has been let down without finding a bottom. Repeated suspicions having arisen of persons murdered by being thrown into this hole, two daring parties caused themselves to be let down ; but at the depth of 1000 feet the lights expired, and they were obliged to return. Poole's Hole, near Buxton, is chiefly remarkable for the large masses of stalactite, and other petrifications with which it is filled.

1814. *On descending into the Low Peak*, a milder grandeur presents itself. The most rugged chains of Derbyshire are interspersed with beautiful valleys ; but none equals that of Matlock, where the banks of the Derwent are bordered by extensive woods, interspersed with the boldest and most varied forms of rock. Dovedale (*fig. 162.*) is a wilder scene, where the river Dove is hemmed in by perpendicular rocks, of forms so bold, and covered with such variety of trees and shrubs, that this has sometimes been deemed the most picturesque spot in England.

1815. *Derby*, the fine capital of this county, has scarcely any thing in common with the other parts. It is watered by the Derwent, now descended from its mountain career, and peacefully flowing to join the Trent, in the broad plain of central England. This town is handsome and well built, without any architectural monuments of the first

class : it has extensive and elegant manufactures.

Silk, introduced at the commencement of the last century, has continued to flourish; and the silk mill of Derby was considered quite astonishing, till it was surpassed by the machinery of the cotton manufacture. In the principal establishment, a single water-wheel produces upwards of 100,000 different movements, by which the silk is converted from the skein, or raw state, to a form fit for the weaver. Porcelain is also manufactured here; and what is called its white ware is considered almost unrivalled. A considerable number of workmen are employed in cutting and polishing marble;

DOVEDALE.

and the Derbyshire spar is fashioned into a variety of beautiful forms by a machine, the varied movements of which are produced by one water-wheel.

1816. *The watering-places* in Derbyshire have the next real claim to notice. Matlock contains mineral springs, somewhat similar to those of Bristol, and reckoned efficacious in consumptive and rheumatic complaints. The accommodations are good and cheap; and the scenery, as already described, beautiful. Buxton, in the High Peak, surrounded by naked mountains, attracts a much greater multitude; and its waters are considered very powerful in rheumatism, gout, and other diseases. The Duke of Devonshire has here constructed a most superb crescent, occupied by inns, shops, ball-rooms, and every thing that can contribute to the accommodation and gaiety of the visitants.

1817. *Other towns.* Chesterfield is neat and respectable, participating in the trade of Yorkshire, on which it borders. Belper is a considerable town; and Cromford, a thriving village, in which Sir Richard Arkwright first applied his wonderful inventions, to be employed on the great scale in a different quarter. Ashbourne is a tolerable town, whence travellers visit Dovedale; Castleton and Tideswell are villages in the High Peak, supported by the mining employment.

1818. *Of seats,* Chatsworth has sometimes been considered the finest in England. It was built by William first duke of Devonshire, in 1702; and is 191 feet square, of the Ionic order, richly ornamented both within and without. There are curious water-works, but in a style now considered antiquated. Formerly it was not distinguished by works of art; but the present duke, after making considerable additions, has both enlarged the mansion, and, we understand, deposited in it a pretty extensive collection of antiquities. It has been almost eclipsed by Kedleston House, whose fine Doric front, 360 feet long, by Adams, is considered one of the finest architectural features in England. Within are some very fine paintings. Sir Richard Arkwright built a fine modern seat near Cromford. Hardwicke Hall is viewed with emotion, as long the residence of the unfortunate Mary; the furniture and the portraits remain, in many respects, in the same state as during her residence.

1819. *Nottingham*, the last of these limitary counties, is likewise fine and extensive. The southern portion is watered by the broad stream of the Trent, its tributaries, and numerous canals. The Vale of Belvoir, to the south-east, ranks with the richest tracts in the island. The north-western part, on the contrary, contains the remnant of the great forest of Sherwood, famed for the revelries of the merry outlaw Robin Hood. Being covered, also, in a great measure, with the ornamented grounds of noblemen of high rank, it is called the "dukeries." There is coal only upon the Derbyshire border. The manufactures of hosiery in this county, Leicester, and Derby, employ, according to Mr. Falkin, 33,000 frames and 73,000 operatives, producing in cotton 880,000*l.*, worsted 870,000*l.*, silk 241,000*l.* The lace trade has become of vast importance, employing, it is said, 150,000 embroiderers in this county.

1820. *Nottingham* is a large town, boldly and picturesquely situated upon the Trent. Its streets are arranged along the face of a hill so steep, that the ground floors of the street behind, in some instances, rise higher than the roofs of those in front. The rocky materials of this hill are so soft and yielding, that they are cut to a great extent into cellars and warehouses. The castle of Nottingham, once of great strength, was demolished by Charles II.; and its churches suffered during the civil wars. The making of stockings, now of various materials, has always been the staple of Nottingham. They are worked on frames, which, in the middle of last century, scarcely exceeded 1200, and at present amount to 10,000. The lace trade recently added is of very great importance. There are stated to be 1240 machines in the town, and 1070 in the neighbourhood; and the lace sold in its market is valued at 130,000*l.* Nottingham has also a great inland trade by the Trent and canals connected with it.

1821. *There are few other large towns.* Newark is renowned in history for its castle, founded by King Stephen, still venerable in ruin; and for a parish church, said to be the finest in the kingdom, almost meriting the rank of a cathedral. *Mansfield*, on a small scale, has the same manufactures as Nottingham. *Worksop* may be called the capital of the dukeries: it is a pleasant little town, with a very fine old abbey church.

1822. *Nottinghamshire may boast some splendid seats*, particularly those around Worksop. Worksop Manor, built but half a century ago by the Duke of Norfolk, contains fine portraits of the Howard family. Clumber Park, nearly of the same date, is fitted up in a magnificent style by the Duke of Newcastle, with a very valuable collection of pictures. Welbeck Abbey, a seat of the Duke of Portland, is noted for its fine stables. Thoresby Manor has extensive and beautiful grounds. In all these, and particularly the last, are found interesting and decaying remains of the trees of Sherwood. Newstead Abbey had been stripped of its fine furniture and paintings before it came to the late Lord Byron, by whom it was sold.

SUBJECT. 4. *The Northern Counties.*

1823. *The northern counties of England* may be described, generally, as reaching from the Humber and the Mersey to the Scottish border. They include the wide extent of *Yorkshire*, divided into three ridings, and of *Lancashire*, *Durham*, *Northumberland*, *Cumberland*, and *Westmoreland*. They form almost an outer kingdom, powerfully influencing, however, the destiny of the rest. During the stormy age of border contest, when every hour might bring in the tide of invasion, the lords or wardens of the marches were necessarily invested with high powers to summon their vassals and neighbours. Accustomed to command troops thus inured to battle, they acted powerfully upon the civil contests in the south; and, in the list of those who braved our early sovereigns, the names of *Northumberland* and *Westmoreland* often stand foremost. Again, at the commencement of the civil wars, this part of the kingdom, destitute as yet of manufacturing cities and thriving burghers, rejected as odious their popular innovations. When the king repaired to York, all the pure and untainted gentry of the north ranged themselves round his standard, and rendered him for some time superior in the field. Strange revolution! Not two centuries have elapsed, and this rude portion of the kingdom has, in wealth, arts, and the immense products of its manufacturing industry, nearly eclipsed those fairer southern portions, by which it was then considered as semi-barbarous.

1824. *Northern England* may be divided into three portions; the eastern, containing pretty extensive fertile valleys on the coast and rivers, but interspersed with large bleak tracts of mountain, moss, and moor. Its ports, on the eastern coast, carry on a thriving trade in coarse, bulky, and useful commodities. The south-western, comprising *Lancashire* and the west riding of *Yorkshire*, is the district which, by the vast produce of its manufactories, leaves far behind it every other, not only in England, but in the whole world. Lastly, there is the north-western, *Cumberland* and *Westmoreland*, or the country of the Lakes, to which Nature, having denied wealth, has granted a higher degree of beauty than any other part of England.

1825. *The counties of Northumberland and Durham* are of the first rank. The whole of their interior is very hilly and elevated; that of *Durham*, indeed, along the upper courses of the *Tees* and *Wear*, rises into mountains. The fall of the *Tees* presents a cascade on a grander scale than almost any other in the kingdom. The interior of *Northumberland* consists chiefly of moors and bleak hills. It contains, however, large improvable tracts, of which the *Northumberland* farmers have happily availed themselves, by introducing all the most improved processes, and the best breeds of cattle, so as to render the district almost a school of agriculture. A breed of black-faced sheep, of the most delicate flavour, is bred on the fine mountain pastures of the Cheviot. The chief wealth of both counties, however, is subterraneous. A species of coarse coal, mixed with lead, every where abounds; and the lead is exported to the extent of from five to ten thousand tons. But within this mineral region there is enclosed a smaller one, reaching from the mouth of the *Coquet* to the *Tees*, a length of about fifty miles, and having its greatest breadth of about twenty miles upon the *Tyne*. Within this tract are found uninterrupted beds of that valuable coal with which London is wholly supplied, and of which great quantities are either sent to other parts of the kingdom, or exported.

1826. *Newcastle* was famed at an early period in the military annals of England. It formed a leading point in the wall of *Hadrian* and in that of *Severus*. Robert, son of the Conqueror, built here a castle of immense strength, more than two miles in circuit, which served long as the main bulwark against Scottish invasion. Scarcely a trace of it now remains; and the occupations of *Newcastle* are entirely changed. Both banks of the river, down to *Tynemouth*, form an immense wharf, to which, by railways and steam waggons, coals are conveyed from the contiguous pits. In 1830, the quantity exported was 867,513 chaldrons, about 2,300,000 tons. *Newcastle* carries on very extensive manufactures, particularly that of glass. There are thirty-one works on the *Tyne*, which in some years have produced glass to the value of 500,000*l.* In shipping it is second only to London, having belonging to it, in 1832, 1077 vessels, of the burthen of 220,784 tons. Foundry, pottery, weaving, are not on a very great scale. *Newcastle* is now, on the whole, a well-built town, though some of the streets are inconveniently steep: it is highly ornamented by the spire of *St. Nicholas*, considered by the best judges as one of the finest specimens of the Gothic. It possesses a literary society, which has published valuable transactions; and an antiquarian society, destined particularly to receive the Roman coins, &c. which are frequently dug up on this line. The large town of *Gateshead*, on the opposite side of the river, though placed in *Durham*, is really part of *Newcastle*, and raises its population to 57,000.

1827. A continued range of great commercial towns cluster thick around *Newcastle*. Near the mouth of the *Tyne* are *North Shields* and *South Shields*, on opposite sides of the river; the latter being in the county of *Durham*. They carry on with activity the coal trade, and the others proper to *Newcastle*; particularly ship-building and the making of ropes and sails. *Tynemouth*, at the immediate opening of the river into the ocean, displays, on a bold promontory, a castle, a light-house, and a fine old abbey; they form a striking and romantic scene, which contrasts with those immediately above. At the mouth of the *Wear*, only seven or eight miles south of that of the *Tyne*, are *Sunderland* and *Wearmouth*,—the one a very great, and the other a considerable, port. Their prosperity is supported by the same great trade of coals, of which in 1832 they sent 600,000 tons to the port of London, two thirds of that which comes down the *Tyne*. They carry on also the same manufactures, particularly ship-building, in which *Sunderland* is supposed to exert a greater activity than any other

place in the kingdom. The bridge there has long been celebrated: it consists of one arch of iron framework thrown across the river, 200 feet span, and 100 feet high, allowing very large vessels to pass under without lowering their sails. "Nothing," says M. Dupin, "can be more striking than this view of the two cities, and the bridge that unites them; that majestic arch drawn against the sky, which allows large vessels to pass under its vault with their sails flying." He afterwards adds, in regard to these ports generally: "It is an admirable thing, within an extent of coast which a man may walk over on foot in three or four hours, to see two great rivers receive 16,000 vessels, and send them away loaded with the produce of their banks. On the same narrow space are six flourishing towns, containing a population of 85,927 persons, all devoted to commerce and industry."

1828. *Durham*, amid these busy scenes, stands isolated, in grave ecclesiastical dignity. It is handsomely built, though on very uneven ground; but its grand ornament is the cathedral, reared in the eleventh century, which, though yielding to some in extent and beauty, is perhaps unrivalled as to its grand situation, ranging along the summit of a precipitous rock eighty feet high above the Wear, which winds along its base. The see of Durham is deemed the richest in England; and the cathedral, besides a dean, twelve prebendaries, and two archdeacons, has attached to it about sixty spiritual servants of various ranks.

1829. *The number of smaller towns* in these counties is still considerable. In Durham, Stockton near the mouth of the Tees carries on the trade of that river; in 1832 it carried 173,000 tons of coal to London, and has also the Baltic trade, and the manufacture of sailcloth and other naval materials. It is described as a very neat, pretty town, with some refined society, and even literary cultivation. Darlington is a neat inland town, with a fabric of linen and some other small manufactures. Hexham, on the Upper Tyne, is the capital of interior Northumberland, and of the grand ancient scene of border debate. Accordingly the whole neighbourhood is filled with ruined castles, warlike monuments, and spots commemorated in tales of feudal contest. Many Roman antiquities are also found there on the line of the Roman wall. Forgetting these scenes of conflict and greatness, the people of Hexham wisely occupy themselves in the manufacture of boots, shoes, and gloves. Alnwick is important only by its castle. Morpeth has a most extensive weekly market for the cattle brought up from Scotland.

1830. *The seats* are chiefly great baronial castles, at the head of which stands Alnwick (*fig. 163.*). This

163

ALNWICK CASTLE.

proud keep of the Percies, when kings trembled at their name, appears to have been a Roman station; but figures first in history under Rufus, when Malcolm III. of Scotland lost his life in attempting to storm it. It covers five acres, and is defended by sixteen towers, rudely adorned by representations cut in stone, of warriors fighting in various attitudes. An expense of 200,000*l.* has been incurred in converting the interior from a feudal castle into the most splendid of modern mansions. The chapel, in particular, presents a most brilliant picture of Gothic decoration; having been copied from what was considered most beautiful in York and other cathedrals. Warkworth Castle, another great seat of the Percies, retains its antique character, and is rendered very interesting by the beautiful hermitage in its neighbourhood.

Near Durham, Lumley, the feudal castle of the Earls of Scarborough, presents entire its august and formidable front. Raby Castle, Howick, Lambton Hall, and Bishop Auckland, are all fine and highly ornamented seats.

1831. *Yorkshire* is next in order: its eastern division resembles the two counties just described; while the western forms part of the great central seat of English manufacture. Amid all its varieties, this great county is considered as decidedly one, and forms, as it were, a kingdom by itself. Yorkshire is supposed to have feelings and interests independent of those which it shares with the rest of England. Its accent and dialect are peculiar. The Yorkshireman has a character of his own, marked by shrewdness, simplicity, good humour, and a species of drollery; so that the London comic stage is considered incomplete without one of his representatives.

1832. *The three ridings of Yorkshire* must be distinguished in giving a view of its surface. The North Riding, which immediately borders on Durham, consists, to a great extent, of moorlands; the hills of which rise often to a considerable height. These dreary tracts spread over the whole riding, so that culture can exist only in the valleys; as in that of York, of the Ure, the Swale, and, above all, in the fine Vale of Cleveland. The minerals, though considerable in quantity, have not been turned to much account. The East Riding, which extends to the Humber, is traversed also by a range of high wolds, which, though rugged, have not been able to resist the energies of British industry; the trees are even made sometimes to afford shelter to the adjoining grounds. Both these Ridings are maritime, and present to the German Ocean high and often precipitous rocks, of which Flamborough Head, with a perpendicular face nearly 500 feet high, penetrated by deep caverns, echoing the cries of numberless sea birds, forms one of the boldest features in English landscape. The West Riding, much more highly gifted by nature, is composed chiefly of a wide, flat, fertile plain, traversed by the Aire, the Calder, and other navigable rivers, which convey its produce to the eastern, and by means of canals, to the western sea. In this favoured tract, accordingly, is placed the immense manufacturing district of Yorkshire. Yet, that the county may still retain its varied character, it has in its extreme west the district of Craven, the most rugged and mountainous of all England; for here rise Ingleborough, Wharfedale, Pennine, each to the height of nearly three thousand feet. Being composed chiefly, too, of bleak heavy ridges, they possess only in a few points the picturesque character of an alpine region. It may be generally observed, that there is scarcely a county in which the spirit of agricultural improvement has been so active as in Yorkshire; and vast tracts of waste and common land, which were deplored by Mr. Young in 1770, are now reclaimed and rendered productive. This is particularly the case in regard to the East Riding, which formerly grew only barley and oats, but now produces a surplus of wheat for exportation.

1833. *The flourishing ports of Yorkshire* are chiefly engaged in the Baltic trade, ship-building, and the whale fishery. Hull, the principal one, ranked during the civil wars as a most important fortress; but its walls are now demolished, and its present distinction is, as the fourth commercial city in England, only surpassed by London, Liverpool, and Bristol. It carries on a most extensive export of goods brought by the interior system of rivers and canals. Those by the Aire and Calder alone, from Leeds, Sheffield, &c., have been estimated at 5,000,000*l.* annually. It is the principal of the whale-fishery ports; though this branch

has lately declined. During the nine years ending with 1818, the average number of vessels fitted out from Hull for the whale fishery amounted to 53 $\frac{1}{2}$; while, in 1830, it sent out only 33. In 1832, it owned 557 ships, carrying 68,892 tons, and there entered its port 1279 vessels of the burden of 192,661 tons, chiefly from Russia, the Hanse towns, the Netherlands, and British America. The merchants of Hull have usefully displayed their spirit by the construction of spacious docks for shipping. The Old Dock, completed in 1778, the Humber Dock in 1809, and the Junction Dock in 1829, contain a space of twenty-three acres. Hull, besides ship-building, carries on manufactures of soap, iron, &c. George Street, Charlotte Street, with other parts of the town, are very handsomely built. Goole, on the Ouse, a little above its junction with the Humber, is beginning to share with Hull in the exportation of woollens. Though a few years ago a mere village, and still, in 1831, containing only 1670 inhabitants, it has two spacious docks, and in 1829 the customs exceeded 40,000*l.*, and the declared value of exports amounted to 625,000*l.* Goods sent from Leeds or Wakefield by rivers or canals can reach and be embarked at Goole in the course of twelve hours.

Whitby is a very ancient town, with the remains of a fine abbey built soon after the Conquest. Its modern importance is derived from large mines of alum discovered in its vicinity two centuries ago. The export of their produce forms a considerable trade, to which Whitby soon added the other branches prevalent on this coast, and became second only to Hull.

Scarborough, romantically situated on a promontory between two rocks overlooking the sea, is the chief watering-place of the north of England.

1834. *York*, the capital, is the first object that strikes us as we proceed into the interior of the North and West Ridings. This celebrated city, though so much eclipsed by several that are only of to-day, still boasts a dignity superior to them, and to almost any other in England. Eboracum was a distinguished Roman station; the emperors Hadrian and Severus each resided in it occasionally, and the latter died there. For some time York disputed with London the distinction of being the capital of England; and when obliged to give up this claim, continued the unquestioned metropolis of the north, till the creative powers of trade raised up rivals to it in the north-west. The houses are high, and the streets narrow; yet, altogether, York is a handsome, respectable-looking old city. It boasts

164

YORK CATHEDRAL.

one feature of almost unrivalled beauty,—its cathedral. (*fig.* 164.) On the exterior all the richness and elegance of Gothic ornament has been lavished, particularly upon the western front and the large window in the eastern. But the interior is without a rival in the empire; its effect is altogether sublime: it seems almost to rise above the works of art, and to rival the grandeur of nature. The numerous windows of painted glass have here nothing gay and fantastic; but shed that dim, solemn, religious light, which is in full accordance with the character of the edifice.

The chapter-house is of singular elegance and magnificence; and, though of great extent, has its roof supported by a single pin. The choir of this splendid edifice suffered severe injury from a fire kindled by the hands of a maniac; but by great exertions has been fully repaired. The small remains of the ruined abbey of St. Mary, and those of several of the twenty-three churches of York, are also deserving notice. There are likewise some elegant modern edifices, particularly the assembly room, designed by the Earl of Burlington, and considered once the finest in England; the county hall, guildhall, the mansion-house, and the museum of the Yorkshire Philosophical Society. York is still a gay town, visited by many of the northern gentry, particularly at the time of its races. It carries on some inland trade by the Ouse, which passes through it.

1835. *In this part of Yorkshire are a number of handsome smaller towns.* Beverley is a well-built place, a sort of municipal capital of the East Riding; and sends a good deal of grain to Hull. Doncaster is one of the gayest and pleasantest towns in the North, and much frequented during the time of its races. Pontefract is also pleasant, surrounded by a great extent of garden and nursery ground, the produce of which is sent to a considerable distance. Scarcely a vestige remains of that immense and powerful keep, covering seven acres, in which Thomas of Lancaster, Richard II., and many other fallen chiefs and statesmen, were immured. The parliament, during the civil wars, having taken it after three successive and arduous sieges, caused it to be completely demolished.

1836. *Leeds* is the capital of western Yorkshire, and, in a commercial sense, of the whole county. Although it was of some note even in early times, its present greatness is modern, and of the most rapid growth. The population, which in 1775 was only 17,117, amounted in 1831 to 123,393; being thus nearly quintupled. A peculiar activity and spirit of enterprise has been observed among the manufacturers of Leeds: it was, doubtless, greatly favoured by the vast extent of inland navigation, which seemed to centre here, connecting it

with the capital, with both seas, and with the counties to the south, from which it derives inexhaustible supplies of fine coal. The woollen manufacture is not carried on wholly in large towns; the cloth is wrought to a certain state of forwardness in the numerous villages, thence sent into Leeds, where it is purchased and worked up into a saleable state. The cloths thus sent in are sold in weekly markets, which were originally held on the open parapet of the bridge of the Aire, a most disadvantageous situation, exposed to weather and passengers. This inconvenience, after being little improved by the raising of temporary stalls in one of the open streets, was at length fully redressed by the erection of the cloth halls, the most remarkable feature in Leeds. That for mixed cloths was built in 1758, that for white cloth in 1775. They form quadrangular edifices round an open area, and are divided into stands, of which in the first hall are 1800, and in the second 1210. These are let at a moderate rent to the owners of the cloth, who, on the ringing of a bell, occupy their stands, and though the market remains open only an hour, goods to an immense value are often disposed of. Although the staple of Leeds and of Yorkshire be common cloth, yet other branches are in some degree included, as sailcloth, cotton, carpets, and superfine cloths. Mr. Drinkwater states the persons employed in the mills for wool at 5290; worsted, 702; flax, 2434; cotton, 80; silk, 158; in all 8664; of whom 5318 are males, and 3346 females; to which may be added 1814 in the suburb of Holbeck. The town of Leeds is mostly well built, with several broad and spacious streets; and the theatre, the new court-house, and the commercial buildings, finished in 1829, are elegant structures. Kirkstall Abbey, three miles distant, presents, in a beautiful situation, the most complete specimen of the architecture of the 12th century that is extant. Before the late parliamentary commission was instituted, it had only five parish churches. The people of Leeds have shown a laudable anxiety to avoid the reproach of neglecting higher and more refined objects in the pursuit of wealth. They have formed a literary and philosophical society, and an institution for the promotion of the fine arts; for the purposes of which a very handsome and commodious edifice has been erected: meritorious exertions have also been made for the education of the poor.

1837. *Of the other towns of the clothing district*, which cluster round Leeds, Wakefield is well built, and beautifully situated on the Calder. It has a fine Gothic church, and a curious bridge, built in the reign of Edward III. It has a cloth market, on a smaller scale, resembling that of Leeds; and, as the surrounding country is equally rich and beautiful, it has also great grain and cattle markets. Halifax, and the whole district about twenty miles round it, has been converted from a desert into a populous and prosperous scene, containing altogether 110,000 inhabitants. Its staples are what are properly called stuffs; shalloons, serges, baize, moreens, kerseys; and it has lately embraced a considerable share of the cotton manufacture. Huddersfield is also a very thriving town, employed nearly in the same branches; and its market hall is supposed, next to that of Leeds, to present the greatest show of woollens in the kingdom. Bradford and Keighley are large towns, which carry on to a great extent the manufacture of worsted: besides which, Bradford has great iron foundries in its neighbourhood. In the southern part of this riding, the manufactures of iron and cutlery take place of those of woollen; and flourish to such an extent, that they are second only to the great iron district around Birmingham.

1838. *Sheffield* is the undisputed capital of this district. It appears to have derived early and considerable importance from the fabrication of arms, an article in universal demand during the days of ancient feud. It has, however, reached a much higher degree of greatness since it quitted this deadly trade, and betook itself to the more useful fabrics of knives, forks, razors, snuffers, scissors, combs, buttons, saws, sickles, and various instruments of husbandry. The art of plating goods with silver, introduced in 1758, by Mr. Thomas Hancock, has been carried to a vast extent. The silver is soldered upon the copper; and the articles are wrought by the hand or stamped. The cutlers of Sheffield keep many hundred patterns of knives, of which some are of the value of seven or eight guineas, containing twenty-eight blades within the handle; while others, after passing through a multitude of different hands, are sold for a penny each. The rapid growth of Sheffield commenced about the year 1750, when a communication was opened with the Continent, and the river Don was rendered navigable to within a few miles of the town. Since that time its advance has been steady; new branches having been constantly adding, and the former ones extending. The houses are chiefly modern, and well built; and the town makes a tolerable appearance, notwithstanding the smoke of the forges in which it is involved. The military barracks erected here form an extensive pile of building. The infirmary is considered equal to any in the kingdom; and great credit is due to Sheffield for the excellence of the schools which it maintains for the education of the lower orders. It supports also many public charities; has a literary society, a mechanics' institute, and a library.

1839. *The rivals of Sheffield* in her manufactures are few and not large. Barnsley produces wire, nails, and other articles, but derives its chief importance from the linen manufacture. Rotherham has been kept alive by the active ingenuity of the family of Walker, who in the middle of last century, established a great foundry for cannon. The view of the melted iron, rolling through the works like liquid fire, is peculiarly striking. The first iron bridge was constructed at the works of Messrs. Walker; and they have since executed those of Sunderland, Staines, and Yarm. Rotherham, being in a fine country, has also a great corn and cattle market.

1840. *The mountain district in the north-west*, comprising Ingleborough, &c., is alike destitute of agriculture and manufactures; yet it abounds in some places with rich pastures, which give some consequence to the cattle markets at Skipton, Settle, and other small towns. Although the region be not generally picturesque, it contains some remarkable caves and striking waterfalls.

1841. *The superb seats which adorn Yorkshire* are so many, that to enumerate even the most distinguished can with difficulty suit our limits. Near the eastern coast is Sledmere, remarkable for having contained the vast collection of books, curiosities, and works of art of the late Sir Mark Masterman Sykes. Castle Howard is a magnificent pile, and is highly noted for its classical collection of sculpture and painting; to which last the late

Earl of Carlisle added several of the very finest pieces in the Orleans collection. Duncombe Park is admired for the noble view obtained from the terrace in front; for the ruins of Rivaulx Abbey, situated in a beautiful vale at a little distance; and for a collection of paintings, not extensive, but highly select. Newby Hall contains an admirable collection of sculpture. Studley Royal is considered an almost unrivalled specimen of an ornamented park. It has the advantage of enclosing within its precincts, besides finely varied grounds and extensive woods, Fountain's Abbey, one of the grandest of monastic remains, covering several acres. At a few miles' distance is Hackfall, a wild woodland dell, leading through a great variety of sylvan and sequestered scenery. Harewood Hall is a splendidly ornamented mansion. Temple Newsome is said to contain a capital collection of pictures. Wentworth House is generally considered the noblest mansion in the north. The principal front extends upwards of 600 feet, forming a centre and two wings, in the middle of which is a fine Corinthian portico. The house contains a celebrated portrait of Lord Strafford, by Vandyke; and other works of art of a high class. The grounds also are particularly fine. Wentworth Castle, now called Stainborough Hall, is also a finely ornamented seat, though not on the same scale. Keveton is a fine old house of the Duke of Leeds, said to be of late a good deal neglected.

1842. *Lancashire*, situated beyond the hilly border of York West Riding, forms the capital or central seat of manufacture for Britain, and even for the world. Under this character we have no doubt that, notwithstanding some temporary difficulties, it will long continue to be distinguished. Lancashire is a long county, reaching seventy miles north and south between the hills and the sea-coast, which is very extensive. Its soil and climate are unfavourable; the upland tracts being rocky and barren, and the coast too low and flat, while the moisture from the Atlantic is injurious to the growth of the finer kinds of grain. The division of property into small portions, and the prevalence of other pursuits, have retarded the improvement of agriculture. The chief activity is displayed around the towns for their immediate supply of milk, butter, fruits, and vegetables, particularly potatoes. But Lancashire has an under-ground product, which she has turned to immense account. Coal traverses in large beds the south and south-eastern parts of the county; and being conveyed by short canal lines to all the great towns, affords cheap and abundant fuel for the steam-engines and other grand manufacturing apparatus. Canal navigation, which originated in Lancashire, has been carried to a greater extent there than in any other part of the kingdom. Besides those smaller canals which connect all the great thriving towns, it has the Lancaster Canal running north and south through nearly its whole extent, and into Westmoreland as far as Kendal; and the still more important line of the Leeds and Liverpool Canal; while, in the southern border, the Grand Trunk connects it with London and the whole centre of England. A most important additional communication has recently been opened by the grand railway, elsewhere described, by which Liverpool and Manchester, so far as respects personal conveyance, are brought almost into contact.

1843. *Manchester*, the centre of British industry, and the manufacturing capital of the empire, is favourably situated on the Irwell; though this stream, navigable for barges, scarcely makes any figure beside the vast artificial lines formed from its waters. Although the cotton manufacture is now widely diffused throughout England, Manchester continues the centre of the trade; receiving and distributing the raw material, collecting the produce worked up in numerous towns and villages, and transmitting it to the various markets. Though a Roman station, and consequently of high antiquity, no monument of importance dates earlier than the fourteenth century. Even at that era it is recorded as an industrious town, carrying on diligently woollen and linen fabrics, the staples of that day. As soon, however, as cotton appeared, Manchester seems to have grasped it as her own, and to have comparatively neglected most other branches. From the middle of last century she has advanced with amazing and accelerated rapidity; and the system of inland navigation having afforded copious channels by which the material can be introduced and the manufactured article exported, every obstacle to the absorption of the whole into this centre was removed. The discoveries of Hargreaves, of Arkwright, and of Crompton, though made in different and distant quarters, may be said to form the basis of the cotton manufacture; and are thus, in fact, the foundations of the greatness of Manchester. Its manufacture, however, does not consist exclusively in the finer muslins and other delicate fabrics, in which Scotland takes, perhaps, the lead; but embraces the plain and useful forms of dimities, fustians, velveteens, checks, shirtings, gingham, diapers, cambric muslins, figured muslins, calicoes for printing, and various fancy goods. The different cotton fabrics generally denominated Manchester goods, are not all manufactured within the town itself, but in the neighbouring towns and districts; and, after being bleached, and some of them printed, are sent in a finished state to Manchester to be sold; the chief *market days* being Tuesdays and Saturdays. Thus Marseilles quiltings, cambric muslins, calicoes for printing, bed quilts and counterpanes, checks, fustians, and shirtings, are brought in from the surrounding towns and villages. A vast deal of yarn is also spun for exportation. Manchester has extensive establishments for printing and dyeing; also, for constructing and keeping in repair steam-engines, as well as other machines employed in manufacture. Even iron foundries are necessary to supply the materials. Other important branches have recently been added. Manchester now rivals Macclesfield and Norwich in the manufacture of silks, and Nottingham in that of lace. In 1832, there were at work in the townships of Manchester and Salford, 96 cotton mills, 16 silk, 4 woollen and worsted, and 2 flax mills. The number employed in cotton factories amounted to 20,585; of whom, 5361 were male and 7035 female adults; 4286 male and 3903 female children. The wages paid to them per month were 40,333*l.*, making about 9*s.* 9*d.* of average weekly earnings to each individual. There were 7174 mule spinners, earning 15,106*l.* per month, averaging 10*s.* 6*d.* each per week; 1497 spinners of a higher class, earning 8491*l.* per month, or 1*l.* 8*s.* 4*d.* each per week. Piecers' scavengers 2944, earning 3287*l.* per month, each weekly 5*s.* 6*d.* In the power looms, women receive 8*s.* to 12*s.*; men, 13*s.* to 16*s.* 10*d.*; dressers, 28*s.* to 30*s.* per week. Manchester is not generally an elegant town; some parts of its interior are narrow, crowded, full of warehouses and factories in huge masses. The entrances, however, have been made handsome; and, in the

extremities of the town, streets of elegant houses have been built for the accommodation of the opulent merchants. It has one handsome Gothic collegiate church of the fifteenth century, and several more modern, that are creditable to the taste of the town. The Exchange, which includes a news-room and a good library, is a fine and spacious building. Still more elegant displays of architecture are made in the Infirmary (which in one year received above 12,000 patients), the Town Hall, and the Royal Institution. The Town Hall contains one of the most splendid public rooms in Europe. The Royal Institution for the Promotion of the Fine Arts was erected by subscription, at the cost of nearly 30,000*l*. The Portico (a news-room and library), and a concert-hall, recently built, are also handsome edifices. The prison called the New Bailey is an immense structure, — the too numerous inmates of which are classed and provided with employment to a considerable extent. Manchester is remarkable for its charitable institutions: as the Commercial Clerks' Society; the Travellers' Society; Strangers' Friends' Society; hospitals of different kinds; and large schools for the education of the poor. The establishment called Cheetham's Hospital, besides maintaining eighty poor children, has a library of 18,000 or 20,000 volumes, containing rare and valuable works. In 1781, a literary and philosophical society was formed at Manchester, and produced several valuable volumes of Transactions, enriched by the contributions of Percival, Ferriar, Dalton, Henry, and other eminent gentlemen there resident. In 1585, Manchester was estimated to contain 10,000 inhabitants, and by 1635 was supposed to have doubled that number. Yet in 1774, the population of the whole parish was not found to be more than 41,000. Since that time, the progress has been continued and rapid. The amount of 142,000 for 1831 by no means comprehends all that may be considered Manchester. The large towns and villages which have sprung up within its parish form really its suburbs, and raise the entire population to 270,000. Of these, the most important are Salford, immediately contiguous, and now raised to the rank of a borough; and Chorlton Row, which in 1801 contained 675 inhabitants; in 1831, as elsewhere stated, 20,565.

1844. *Huge towns, resembling cities, devoted to the cotton manufacture*, are found in every direction round Manchester. To the north are *Blackburn* and *Bolton*; the former chiefly employed in the branch of printed calicoes, which are supposed to be produced to the annual value of 2,000,000*l*. Hargreaves was a native of this place. A great advantage is derived from the Leeds and Liverpool Canal passing close by it. Bolton is a town anciently of some strength, but now supported entirely by industry. Some of the greatest improvements in the cotton manufacture, and the processes connected with it, have been made by Arkwright and Crompton, residents in this place. Preston was only considered a genteel retired town till within these last forty years, when the single exertions of Mr. John Horrocks made it a flourishing seat of manufacture. It continues, however, to be distinguished among all the cotton towns, as a gay handsome place; and has the advantage, or disadvantage, of electing two members on a basis of almost universal suffrage. Wigan is a large town, of some note in history, and which adds to those of cotton and linen some manufactures of brass and pewter. Bury, very near Manchester, besides extensive cotton works, has some of woollen. Oldham was early a place of some consequence, carrying on a large fabric of hats; but the introduction of the cotton manufacture has caused it to make an astonishing progress, so that in thirty years it has nearly trebled its population, and the parish, including Pilkington, Crompton, and other towns, contains 67,500 inhabitants. There are here now 65 cotton mills and 140 steam-engines, almost all erected during the present century. To this long list may be added Chorley, a neat thriving little town; Middleton; Clitheroe, where there is an old castle; Garstang, and several other towns.

1845. *Some large towns employed in other manufactures than those of cotton* lie on the borders of Lancashire. Rochdale, near the western point of Yorkshire, and in character a Yorkshire town, has for its staple woollen stuffs and flannels, of which 8000 pieces are made weekly: fifty-seven steam-engines are employed here, and about 84,000 lbs. of cotton yarn spun in the week. This place, composed of the townships of Spottland, Castleton, and Wardleworth, has of late been greatly improved. Warrington, on the south border, stands on the Mersey, which is navigable for vessels of eighty tons from Liverpool. It is ancient, and in Henry VIII.'s time was superior to Manchester; but though slowly advancing, it is now left far behind. Its staples of sailcloth and coarse linens have been exchanged for cotton, to which it adds glass and pins. Prescott, on the same line, is noted for the making of watch wheels, springs, chains, &c. several of which have been invented and improved by its workmen. Near it, at St. Helen's, is a great manufactory of plate glass, erected at an expense of 40,000*l*. and employing 300 persons.

1846. *Liverpool*, the commercial capital of Lancashire, is, if possible, a still grander object, and far surpassing indeed every other seaport, with the exception of the metropolis. Nothing can be more remarkable than the contrast of its present state with its humble origin. In the sixteenth century, it is described as a small place, with only a chapel, having no parish church within four miles. It had then 138 inhabitants, and two or three ships, whose aggregate tonnage was 223 tons; and in a petition to Elizabeth, about the year 1578, it is styled, "her majesty's poor decayed town." It continued gradually to increase during the seventeenth century, till, in 1700, it was raised to the dignity of a parish and had 5000 inhabitants. Since that time it has advanced with rapid and accelerated steps; in 1730, it had 12,000; in 1760, 26,000; in 1700, 56,000 inhabitants; but the most rapid growth has been between 1811 and 1821, when it rose from 94,376 to 141,487. The increase to 165,000 in 1831 appears less rapid; but in fact, the population during this period has overflowed into the adjacent villages, and swelled them into large towns; Toxteth-park increased from 2069 in 1801, to 24,067 in 1831; West Derby, Kirkdale, Everton, form in fact the suburbs of Liverpool, and, added to it, make an amount of 203,000. There must always have been a considerable port at the mouth of the Mersey; but this estuary, in its natural navigation, could never come in competition with the Humber or the Severn. When, however, its disadvantages as a seaport were partly removed, by the formation of docks, — and, much more, when it became the basis of a canal system reaching eastward to the German Ocean, and southward to the Thames, — Liverpool could communicate

with an immense interior circle. It derived benefit, above all, from the cotton manufacture established, on such an extensive scale, in the country immediately behind; the materials of which were brought to Liverpool from the opposite side of the Atlantic, and the finished fabric thence exported, partly to the same quarter. At the same time Liverpool imported, for a great part of England at least, articles of consumption from America and the West Indies. It found also a most extensive employment in bringing grain and provisions from Ireland, and returning salt, coals, and pottery. The merchants of Liverpool, meanwhile, were most active in improving these circumstances, particularly by the construction of that immense line of docks, which M. Dupin has described with such admiration. A dock, or space enclosed all round, and fed with sluices, in which the vessels while they receive or discharge their cargoes are kept regularly afloat, without being exposed to swell, tide, or current, is an obvious improvement upon the best natural harbour. The expense, however, is great; and it was not till 1710 that Liverpool began the first dock in Britain, called the Old Dock, which has recently been filled up. Twenty years were employed in its completion; and a still longer time in that of the next, or the Salhouse Dock. The others were, however, constructed on a more extensive scale, and with greater rapidity: — George's (II.) Dock; the King's Dock, for Greenland ships and tobacco; the Queen's Dock, directly for the Baltic and North American trade. On a still larger scale have been constructed the Prince Regent Dock, opened in 1821, and the Clarence Dock, in 1830. The Brunswick Dock, intended for the accommodation of vessels with cargoes of timber, is in progress, and will nearly complete the present plan, when the whole area of water in the docks will exceed 90 acres. In 1832, there belonged to it 853 registered vessels, of the burthen of 166,028 tons. The customs paid at the port amounted, in 1733, to 92,466*l.*; in 1765, to 269,000*l.*; in 1785, to 680,000*l.*; in 1810, to 2,675,000*l.*; in 1824, to 1,984,000*l.*; and in 1832 they had risen to 3,925,062*l.* The following are stated as the leading articles of import in the year 1830: — 792,350 bags of cotton, 510,000 hides, 42,000 hogsheads of sugar, 8000 hogsheads of tobacco, 300,500 barrels of flour, 7800 casks and 7300 barrels and bags of coffee, 27,000 casks of palm oil, 900 serons and 1430 chests of indigo, 12,000 puncheons of rum, 31,200 bags of rice, 22,500 barrels of American ashes, 42,500 barrels of tar, 51,000 barrels of turpentine, 6200 tons of logwood, 5650 logs of mahogany. The dock duties, which in 1800 were only 23,379*l.*, amounted, in 1832, to 170,000*l.* In 1832, the ships entered inwards were 10,266, tonnage 1,361,000; outwards, 8717 ships, tonnage 1,218,645. Of this, 610,000 tons were from foreign parts, chiefly the United States and British America, the rest coasters, of which 386,000 were from Ireland. The value of agricultural produce from that country amounted to 4,444,000*l.*

Liverpool has numerous lines of packets to all the principal foreign ports. Every month four sail to New York, two to Philadelphia, one to Boston, two respectively to Rio Janeiro, Genoa and Leghorn, and to Lisbon; one every three weeks to Oporto. The New York packets are first-rate vessels, containing splendid accommodations for passengers, and the value of goods conveyed in one of them has been known to exceed 140,000*l.* Trading vessels also are continually sailing to the above and to all other commercial places throughout the world. An almost daily communication is maintained by steam packets with Dublin, Belfast, Glasgow, Whitehaven, and all ports of any consequence in Ireland and on the western coast of England. The solid construction of its docks; the powerful iron gates by which they are enclosed; the long covered ways where the goods may be landed without injury from the inclemency of the weather; the immense magazines, some rising to the height of 12 or 13 stories, — all denote a gigantic industry and a magnificence, which spares no sacrifice to attain objects of public utility. The inhabitants of Liverpool have generally shown the same spirit in their other arrangements as in those connected with trade. The town is well lighted with gas. The public buildings have an elegant and classical character, almost peculiar to Liverpool. The Town-hall (*fig. 165.*) is a fine Grecian edifice, ornamented with a superb cupola and appropriate statues. The Exchange forms behind it an elegant square, in the midst of which is a sculptural composition, by Westmacott, representing Nelson and his victories. The new edifice erected for a market is, perhaps, the most spacious and commodious of any employed in the kingdom for that purpose. There are also several elegant modern churches, one formed of cast-iron. The finest view of Liverpool is obtained from the sea, where the vast height and extent of the exterior dock wall, the forests of masts above, and the town behind, make a most imposing appearance. The charitable institutions are administered on a great scale, and with activity. Foremost stands the Blind Asylum, the first established in England, which continues to be conducted with unequalled success, receiving inmates from all parts of the kingdom. The infirmary is in a very spacious and airy situation; and, among the other institutions

165

TOWN-HALL, LIVERPOOL.

common to great towns, the Strangers' Friends' Society distinguishes itself by its generous exertions. The English mercantile towns generally show a zeal to combine intellectual pursuits with those of wealth; but none, perhaps, so successfully as Liverpool, — one of whose merchants, while carrying on an extensive business, produced works which rank him among the most classical English writers. Although this example be single, it is connected with a general spirit, which displays itself in the liberal procedure of several individuals; in the Lyceum and the Athenæum; two public libraries and literary institutions, supported by subscription; and in a botanic garden, which ranks as the first that was formed, and at least the third as to eminence, in the kingdom. It is at present about to be transplanted to a more commodious situation. Both

the Athenæum and botanic garden owe their foundation to the public spirit and the munificent example of Mr. Roscoe, who had also the magnanimity to exert his powerful talents for the abolition of the slave trade, in a town long devoted to that traffic.

1847. *Lancaster*, though the county town, has been almost overlooked amid the new and vast objects which have sprung up within its domain. Yet it is a fine, handsome, small town, built of a beautiful free-stone, which never moulders or blackens, like that of Portland and Edinburgh. The Town-hall and some other buildings are handsome; but the castle (*fig. 166.*) forms one of the grandest monuments of the feudal

LANCASTER CASTLE.

166

age. Its vast extent; its commanding site; the greatness of all its features, even now, when three of its seven towers are fallen into ruin; produce the most powerful impression. It has been converted into a well-arranged prison for the county. Lancaster, though no longer the chief seat of commerce on this coast, and though its river, the Lune, is not navigable for vessels of more than 250 tons, still possesses 73 sail. It builds some ships. It makes sailcloth, and even a little cotton. About a mile from it, the Lancaster Canal is carried over the Lune by a very noble aqueduct bridge.

1848. *The counties of Cumberland and Westmoreland, or the country of the Lakes*, form a bold and peculiar region, to complete the picture of the north of England. It presents a striking contrast to those recently surveyed; being enriched neither by natural wealth nor by the wonders of human industry. Wide

ranges of high and rocky mountains, enclosing long lakes and narrow vales, afford scanty space for the plough. A great proportion of these fells and moors is absolutely barren; in the more favoured spots the herbage is often scanty; and even the arable tracts are, in general, fit only for the coarser grain of oats. The new modes of agriculture have penetrated slowly; the lands being, in a great measure, divided among estatesmen, or small early proprietors, like Scottish lairds, some of whom even trace their possession to a date anterior to the Conquest. Still, the pride of these regions consists in the beauty with which nature, in the absence of more solid gifts, has lavishly adorned them. The multitude of mountains crowded together, their bold, perpendicular, and often projecting forms; the pleasing though not extensive lakes, and soft pastoral valleys, which they enclose, with the rich shadows and varied tints that adorn them; all these, which mark a region of alpine wildness, mingled with features of cultivated nature, render this the most beautiful country of England, and the favourite resort of all the admirers of the picturesque and sublime.

1849. *Three divisions* are distinctly seen in these counties, reaching from north to south. I. A plain eastward of the mountains, through which the high road runs by Kendal and Carlisle to London. II. The mountains and lakes, occupying the larger portion of their surface. III. A sea-coast, containing some harbours of importance.

1850. *The first part* consists of a plain, which, though narrow, is in many places fertile; and contains some large towns. In the northern part is "merry Carlisle," long distinguished in the border annals, and the scene of interesting events in the contest of 1745. Carlisle being a military post of the first consequence, its castle and walls were considered a model of strength, according to the ideas of the middle ages; and, though of no importance at present, they are still maintained. The cathedral is an ancient elaborate edifice, still nearly entire; but in which the heavy Saxon style too much prevails. Carlisle is finely situated on a height overlooking a verdant plain, in which the Eden and the Caldew unite their waters. It has of late begun to carry on some manufacture, chiefly cotton; also woollen, linen, and a few minor articles. A canal connects it with the Solway, and enables it to employ some shipping. Eastward from Carlisle is the great debateable line; and near Brampton is Naworth Castle, that powerful station where Lord William Howard undertook to bridle the licence of the border. Yet, however strong, it forms rather a dark border keep, than a display of feudal grandeur. Lord Howard's apartments, which, with their books, furniture, and armour, remain almost undisturbed, are separated by four strong doors from the rest of the castle; and secret passages lead to every part, and to the dungeons beneath. The high road from Carlisle southward has, parallel to it, the beautiful and rural valley of the Eden. Penrith, a neat little town, commands from its beacon, and even from the road above, a noble view of the Cumberland Fells. Considerably farther south is Kendal, the chief town of Westmoreland; a considerable place, with an old manufactory of woollens bearing its name, and some of cotton and leather. Burton and Kirby Lonsdale are small neat towns on the border of Lancashire.

1851. *Our second division* comprises the country of the Lakes, forming the peculiar characteristic of the country, and chiefly distinguished by its scenery. Ullswater, the first approached from Penrith, is a long narrow sheet of water (*fig. 167.*) divided into three reaches.

ULLSWATER.

167

The mountains are very numerous, steep and lofty, not broken or impending, but of a peculiarly bold and swelling form. The two highest on the lake, and in the region, Helvellyn, and the square rocky mass of Stone Cross Pike, appear at first distant, and behind lower hills. As the traveller advances, their apparent dimensions increase; and at the end of the second reach they display themselves in their full grandeur, rearing their almost perpendicular

forms to an amazing height above the wooded hills which cluster round them. Opposite rises the immense precipitous steep of Place Fell; and the whole produces a scene of

solemn and simple grandeur, which can scarcely be surpassed. At the end of the third

KESWICK LAKE.

broken, shattered, impending, shooting into a thousand fantastic shapes; and though they

LODORE WATERFALL.

and from behind the grounds of Calgarth, where all the features are on the greatest

WINDERMERE LAKE.

admirers of nature. In this district, the only places to which the name of towns could be given are Keswick on Derwentwater, and Ambleside on Windermere; yet even these are only large villages, supported by the resort of travellers, and by some persons of distinction who are induced to reside there by the beauty of the neighbourhood.

1852. The third division consists of the sea-coast. The most considerable port is Whitehaven, which two centuries ago was a mere fishing-town; but has become flourishing in consequence of the immense coal mines found and worked in its immediate vicinity. Some of them have a depth of 320 yards, supposed to be greater than any other in the world; and some extend several miles beneath the sea. The total quantity worked is estimated at 100,000 chaldrons, chiefly exported to Ireland: besides which, Whitehaven has pushed its trade to Africa, America, and the West Indies; and carries on much ship-building. Workington combines a con-

siderable extent of the same coal trade, with some sail-cloth, and a fishery of salmon, which is sent even to London. Cockermouth, somewhat inland, at the confluence of the Derwent, has a manufactory of coarse woollens and linens. Maryport has some cotton manufacture, as well as some trade and a fishery.

1853. *Of the seats*, Greystoke Castle is a noble mansion, originally built by the Danes, from whom it descended to the Duke of Norfolk, and contains fine portraits, and memorials of Mary of Scotland. Lowther Hall is celebrated for the noble woods which surround it. Armathwaite and Corby Castle, to the latter of which adjoins Wetherall Priory, are admired for the extreme beauty of their situation on the Eden.

SUBSECT. 5. *Western Counties.*

1854. *The western counties* form the last division of England Proper. The term is of somewhat vague application; but we here use it as applying to all the counties south of the Mersey, which form the western boundary of England. This extensive line has scarcely any character which can be said generally to apply to it. We mention *Cheshire*, *Shropshire*, *Hereford*, and *Monmouth*, as bordering on Wales, and the last three partaking somewhat of its rude and romantic character; *Worcester*, *Gloucester*, and *Somerset*, occupying the fine valley of the Severn, — a region filled with commerce and cultivation, and containing several great cities; lastly, *Cornwall* and *Devon*, the extreme corner of England, but marked by a mild climate, rich mines, and a surface agreeably diversified.

1855. *Cheshire*, immediately south of the Mersey, though bordering on Wales, has nothing of a rugged character, and sees only at a distance the vast mountains of Montgomery and Caernarvon. The soil is generally fit for all the purposes of agriculture, particularly in the valley of the Dee: but the dairy is the branch pursued with peculiar success; and it produces the cheese which, bearing the name of the county, equals in richness, though not in delicacy, any other in Britain. There are valuable mines of coal, and some of iron; but the mineral substance of which Cheshire chiefly boasts is salt. The pits were discovered about a century and a half ago, at Northwich, Middlewich, and Nantwich, and have proved of the highest importance to the nation, at once for internal consumption, for the curing of fish, and for exportation. Cheshire has manufactures of gloves, silk, silk-twist, cotton, and a number of detached articles, but not sufficient to constitute it a manufacturing county.

1856. *Chester* is, perhaps, the city in Britain which bears the most venerable character of antiquity. The very name implies a Roman camp, the form of which is still preserved in the direction of its principal streets. The effect is heightened by the mouldering red stone, of which its most ancient edifices are built. The principal streets have a very peculiar structure. The lower story, which has been hollowed out of the rock, consists of shops, above which is a paved way covered by the projecting upper story; but the middle part of the house appears thus retired from the open street behind this species of arcade. The arrangement is neither very elegant nor very convenient. The castle of Chester presents a very complete specimen of early military architecture, though the keeping is not very strictly preserved. Connected with it is a range of very handsome Grecian buildings, containing the barracks, county hall, and county gaol. The cathedral, though not ranking with the first in the kingdom, displays, however, considerable grandeur, and has a very elegant chapter-house. The improvements on the Dee enable vessels of 300 tons to come up to Chester, which has 62 vessels, of above 4000 tons; yet its trade with Ireland has been transferred to Liverpool. Gloves, lead, shot, and some other fabrics, do not make it a manufacturing town.

1857. *Of the other towns*, the most remarkable are those near which the salt mines are situated, particularly Northwich. There are fourteen pits of rock salt, and between thirty and forty of brine salt. The rock salt is hard and brown; the pits, after being dug to a certain depth, are excavated horizontally, leaving a portion of the salt for a roof. They thus form apartments, often of more than an acre in extent; and the reflection of lights from the mineral, like that of numberless precious stones, produces a magical effect. The pits of Middlewich are on an inferior scale; and those of Nantwich, though the most ancient, are become now of secondary importance. On the extreme eastern border are Stockport and Macclesfield, two large towns, which have flourished greatly in consequence of the introduction from Lancashire of the cotton manufacture, to which Macclesfield adds some branches of that of silk.

1858. *Among the seats* are Eaton Hall, a magnificent Gothic edifice, which Earl Grosvenor has erected at an expense, it is said, of 400,000*l.* Tabley Park is a fine Doric edifice; and Marbury Hall contains some valuable sculpture.

1859. *Shropshire*, or *Salop*, is a large and interesting county, consisting chiefly of a wide plain watered by the Severn, which, issuing from Wales, follows first an easterly, and then a southerly course. The soil is mostly well fitted for agriculture, which is carried on in a respectable manner, without any extreme skill or peculiar processes. On its eastern border it shares to a great extent in the mineral wealth of Staffordshire, coal and iron. These are carried on in a remarkable manner at Colebrook; a deep-wooded vale on the Severn, here traversed by the first iron bridge erected in the kingdom. So well is the spot arranged, that, notwithstanding the gloomy fire and smoke of the works, it still retains much of its picturesque effect. This county is also interesting to the student of English history; many spots having been the scenes of remarkable events, on which the destinies of the kingdom have depended.

1860. *Shrewsbury*, the capital, is particularly rich in memorable recollections, and forms a sort of key to the history of England during its turbulent era. Being the strongest fortress on the western marches, it became a rendezvous of the royal army, both for overawing

the Welsh, and for northern expeditions. It is well situated on a peninsular eminence, overlooking the Severn, of which, and of the fine country watered by it, a noble view is commanded from the ramparts. Though a striking, it cannot be said to be a well-built city, as many of the streets are narrow, winding, and irregular, and the old and new buildings too closely intermingled. Only a small part of the castle remains; giving, however, an idea of its great strength in former times. St. Mary's church is elegant and entire. One of the most remarkable objects is the free school, founded by Edward VI. and Queen Elizabeth; a spacious and lofty structure, which has produced several eminent teachers and pupils. Shrewsbury is praised for its house of industry, and for the arrangement of its county gaol. Placed at the entrance of Wales, it formerly carried on all the trade of that principality, and has still a considerable share of it, as well as of the river navigation down the Severn.

1861. *Shropshire has also Ludlow*, an ancient and memorable town, not unfrequently the residence of royalty, and the regular station of those powerful officers the Lords Presidents of the Marches. The castle, defended by thick walls of great extent, and placed on a wooded rock overhanging the Terne, was considered one of the strongest places in the kingdom. In its vicinity occurred many of the most distinguished events in the contest between the houses of York and Lancaster. It was afterwards dismantled; yet remained a splendid private mansion, in which Milton's "Comus" was first performed, and where Butler wrote a part of his "Hudibras." It is now entirely roofless and covered with ivy, but still adorns the town, which is well built and pleasantly situated.

1862. *The other towns* are not very remarkable; but we may mention Broseley, in the centre of the coal and iron works; Bridgenorth, which carries on a considerable trade on the Severn; and Wellington, a good market town near the Wrekin. Ellesmere and Oswestry are agreeable towns on the Welsh frontier, and carry on a thriving trade by means of a canal which communicates with the Grand Trunk.

1863. *Hereford and Monmouth*, two demi-Welsh counties, fill the interval from Shropshire southwards to the British Channel. Being traversed first in an easterly, and then in a westerly direction, by the Wye, the most picturesque of the English rivers, they may vie in beauty with almost any part of the kingdom. Without the bold and sublime features of Cumberland and Wales, they are broken into swelling hills, covered to the summit with trees and cultivation, rich with luxuriant foliage, and affording an inexhaustible variety of delightful prospects. The soil is in many places very favourable, yet the culture of grain has not made very great progress; though the district, being almost entirely agricultural, affords a certain surplus for the Bristol market. But the chief care and success is in the rearing of fruit, and the whole county is as it were covered with orchards. Hence Hereford draws its staple production of cider and perry, in peculiar abundance and perfection. The crop is precarious; but in a good year the produce of an acre will be from eighteen to twenty-four hogsheads, each requiring between twenty-four and thirty bushels of apples. The liquor is sometimes of such very fine quality, that it will sell from the press at 20*l.* a hogshead. It is chiefly sent to London and Bristol, whence a large proportion is exported to America and the West Indies. The western district of Hereford produces also a large quantity of hops,

and has one of the finest breeds of cattle in the kingdom, both for draught and feeding, in which latter capacity they often reach the metropolis. The breed of sheep, called Ryeland (*fig. 171.*), besides the excellence of their flesh, bear the very finest wool in the kingdom. Monmouth is not so fertile, yet has a good breed of cattle, and particularly of mules; and supplies Bristol plentifully with fruit. Its chief wealth, however, is mineral, coal being most abundant; and iron works are established to such an extent, that they have been known to produce a thousand tons in the week.

171

RYELAND SHEEP.

1864. *Of the towns*, Hereford bears venerable marks of antiquity, particularly its cathedral, notwithstanding the fall of its principal tower. From the defects, however, in the navigation of the Wye, it has never attained to much commerce. Ross, once the residence of Mr. Kyrle, celebrated by Pope as "the Man of Ross," is a beautiful village, considered as a sort of centre of the picturesque scenes of the Wye. Leominster and Ledbury are small towns, which have lost a great part of their former manufacture of cloth.

172

TINTERN ABBEY.

1865. *The towns of Monmouthshire* are small, but its local features are striking. The capital is of little extent, and has only a limited trade along the Wye; but its situation, in the midst of a delightful country, has attracted some neighbouring gentry, who have built good houses. There are still remains of its once powerful castle, and of a Benedictine priory. A few miles from Monmouth is Tintern Abbey (*fig. 172.*), the most picturesque, perhaps, of all the English monastic remains. This arises, not

merely from its extent and beauty, although these be great; but from its roofless and ruined state, whence the

173

RAGLAND CASTLE.

presents an appearance venerably sublime, not only from the town, but for many miles round. Near Chepstow are the grounds of Persfield, the views from which over the Wye, bordered by immense woods and precipices, the Severn and its rich valley, and the many picturesque objects which fill the landscape on every side, are considered almost unrivalled. Farther to the west is Caerleon, once the celebrated capital of the ancient Britons, and a great Roman station. But though huge fragments of wall are still found scattered about, there is no ruin left in tolerable shape or preservation. Uske, a rude old town, on a rapid river of the same name, has considerable remains of a strong castle. Abergavenny, higher up the Uske, is an agreeable and frequented town, surrounded by fine scenery. Newport, near the mouth of this river, has a little trade in articles brought down its course. Pont-y-pool, farther west, has lost, in a great measure, its tin and Japan fabrics; but it is in the centre of the great coal and iron works in the western part of the county.

1866. *Worcester and Gloucester*, two fine counties, lie eastward of the above. They occupy the lower valley of the Severn, which there becomes a river of the first magnitude. This valley is broad, smooth, and fertile, yet nowhere degenerates into a dead unvaried level. Worcester has, on the west, the Malvern Hills, of whose waving summits some rise to the height of nearly 1500 feet, and afford prospects, rarely equalled, over an extent of rich and cultivated country, bounded by distant hills. Gloucestershire, again, has to the east the Cotswold Hills, more rugged, though not so elevated; while to the west are the rugged remains of the Forest of Dean. Worcestershire has, besides, the valley of the Lower Avon and of Evesham, which, especially the last, are famed over the kingdom for their beauty and fertility. The vales of these fine counties are fitted for produce of every description, — grain, fruits, pasturage, with some preference of the two latter. Cider and perry are produced every where in the utmost abundance, and often of superior excellence, though not quite equalling that of Hereford. Gloucester, however, is particularly distinguished for its dairies, which produce that rich cheese well known under its name. The best, or double Gloucester, is produced in the vale of Berkeley, situated along the lowest part of the course of the Severn. The mineral productions are not extensive; they are chiefly the salt of Droitwich, and a considerable quantity of coal, and even of iron in the forest of Dean. Both counties have flourishing manufactures, though not on the vast scale of the northern districts. Gloucester, in particular, has a very extensive fabric of fine woollens, carried on through numberless villages, in what are called “the Bottoms,” a range of territory along the lower part of the Cotswold Hills. Its scarlet and blue woollens are in particular repute. There are besides a number of detached manufactures, which will be noticed under the places in which they are carried on.

1867. *Worcester* is a considerable and very handsome city, the principal streets being spacious and regular, with many good houses, and presenting a general air of neatness and comfort. It is of high antiquity, the cathedral (*fig. 174.*) having been founded in the 7th century, by Ethelred, king of Mercia. The original

174

WORCESTER CATHEDRAL.

edifice sustained various disasters; and the present structure was almost entirely erected in the thirteenth and fourteenth centuries. It is of great extent, simple and august, without the rich ornament which distinguishes some others. It contains the tomb of King John, one of the most ancient in England; also that of Prince Arthur. Worcester is chiefly noted in history for the great battle in which Cromwell totally routed the Scots army, and compelled Charles II. to quit England as a fugitive. The city has lost its woollen manufacture; but has still one of porcelain, the finest in the kingdom. Fifteen different materials are used, chiefly white granite, and steatite from Cornwall; and every piece passes through twenty-three hands before it is brought to perfection. Mr. Warner, in his tour, mentions a set of coffee cups then making for the Grand Seignior, and representing the battle of the Nile, each of which was of the value of 10 guineas; yet of such surpassing beauty, that the price appeared moderate. Gloves are also made; and there is a considerable trade up and down the Severn.

1868. *Of other towns in Worcestershire.* Kidderminster is large and flourishing, in consequence of a very extensive manufactory of carpets. Bromsgrove carries on the making of nails and needles; and Stourbridge that of glass. Droitwich is noted for its salt springs. They are covered with a deep stratum of gypsum: and for a long time the salt was made only from the brine which penetrated this bed; but, about a century ago, it was bored through, when the brine rushed up in vast quantities, and a large salt river was found to flow beneath. Thus the salt can now be procured in any quantity, and supplies a great part of England. Evesham and Pershore are large villages, noted for the beauty of their situation.

1869. *Gloucester* is also an ancient and fine city, though not quite so large as Worcester. It bears, in the arrangement of its streets, the marks of having been a Roman station. It was formerly, also, a place of great strength. The manner in which it frequently baffled the utmost efforts of Charles I. was one of the circumstances which contributed most to the downfall of the royal cause. The most conspicuous feature at present is the cathedral, built in the Saxon and Norman styles, between the 11th and 13th centuries. The beautiful lightness of its tower; its east window, said to be the largest in the kingdom; and its whispering gallery; attract peculiar notice. The gaol, built at an expense of 40,000*l.*, afforded one of the first applications of the beneficent principles of Howard. Pins are the chief manufacture of Gloucester; and, small as the article is, the sale is so great as to render the amount it returns considerable. Its trade has been much obstructed by the bad navigation of the Severn; but since the parallel line of the Berkeley Canal has just been completed, by which large ships can come up from the Channel, Gloucester is placed almost on a footing with Bristol.

1870. *Cheltenham*, by the fame of its waters, and its attractions as a place of fashionable resort, has become a greater and more crowded place than Gloucester. The virtue of these waters had been repeatedly noticed; but it is only within the last forty years that they have attracted such crowds of visitors. In 1780 there were not above thirty lodging-houses; now there are several thousands. The waters are at once saline and chalybeate; and, being thus both tonic and aperient, are efficacious in indigestion, biliary affections, and similar disorders. There are several springs in different parts of the town, the proprietors of which vie with each other in the elegance of the rooms, and the accommodations. The town, though of brick, and without any striking features, is light, gay, and commodious. The immediate vicinity is level; but, at a little distance, a branch of the Cotswold Hills gives variety to the scenery. Upon the whole, Cheltenham seems now to rank second only to Bath, both as a resort for invalids and a gay rendezvous of the fashionable world.

1871. *There are other interesting towns in Gloucestershire.* Tewkesbury has in close vicinity the "Bloody Meadow," on which was fought the great battle which finally crushed the fortunes of the house of Lancaster. Placed at the junction of the Severn and Avon, it is a venerable old town, containing in the Abbey church a remnant of that grand monastery, of which the superior, being a mitred abbot, sat in the House of Peers. Cirencester, a town of great historical name, covers only part of its ancient site, but contains one of the finest parochial churches in the kingdom. Stroud is the centre of the woollen manufacture carried on, not in itself, but in the surrounding valleys, and raising the population of the parish to 42,000. It is carried on also at Uley, Dursley, and Wotton under Edge. Bristol we consider as belonging to Somerset.

1872. *Of the seats in this part of England,* the most interesting is Hagley, the grounds of which Lord Lyttelton adorned with classic taste; while he enriched the interior with portraits of his illustrious friends, and with other paintings. Near it is the smaller, but equally interesting, spot of the Leasowes, embellished by Shenstone with all the taste of a poet. Berkeley Castle is a grand castellated edifice, almost as old as the Conquest, and the scene of Edward II.'s death; retaining still its antique character. Crome Park, Oakley Park, and Badminton Hall are superb mansions, in which are some interesting works of art.

1873. *Somerset* is a large county, whose coast commences where the Severn opens into the Bristol Channel, the windings of which it follows in a westward direction. The county extends also to a considerable depth inland. Its surface is exceedingly varied; and contains copious specimens of the best and the worst, the smoothest and most rugged, situations and soils. It has vales almost as extensive as those of Gloucester, yet is crossed by long ranges of those steep and rugged hills which pervade all the extreme west of England. The most easterly are the Mendip Hills, dark and barren, but rich in mineral stores; broken also at different points into deep chasms and caverns. Farther west are the Quantock Hills, — separated, however, by fine valleys or *coombs*; while on the borders of Devon lies Exmoor Forest, the most elevated of all these tracts — its highest point, Dunkerry Beacon, being 1668 feet high. There are, besides, between the hills and along the coast, marshes of great extent frequented by clouds of wild geese, the feathers of which are a staple product; but, by extensive drainage, many of these marshes have now been converted into rich pasture. Somersetshire contains many fine arable tracts, yielding in the lower grounds wheat, in the higher, oats and flax. The prevailing husbandry is pasturage, chiefly of rich natural grass; and, besides a number of cattle sent to the London markets, the dairy is a great branch of industry. Cheddar cheese is considered equal to any in England; and a great quantity of what is called Gloucester is produced in Somerset. Bath and Bristol are also well supplied with excellent butter. The orchards are extensive, and cider and perry nearly as abundant as in the counties on the Severn. The Mendip Hills yield excellent coal, lead of fine quality, and calamine. The manufactures are considerable, both woollen and linen; the former chiefly of the finer sorts; the latter, mostly dowlas, tickens, and sail-cloth.

1874. *Bristol*, since it is here attached to Somerset, must hold the first place. This city, already distinguished in the reign of Henry II., ranked long as second to the metropolis in commercial importance; but in the course of the last century, it has remained nearly stationary in extent and population, though not in wealth. In 1736, it had 80,000 inhabitants; in 1821, 87,771, but in 1831, with its suburbs, 104,886. It has still a very extensive trade, chiefly with Wales, Ireland, and the West Indies. Nor does its spirit seem abated; since, in 1809, it completed, at an expense of 60,000*l.*, a series of extensive improvements, by which the rivers Avon and Frome were spread out into two vast basins, for the commodious reception of vessels. The manufactures of Bristol are very considerable; the glass-works are twenty in number; its brass founderies the most extensive in the kingdom; to which it adds patent shot, pottery, &c. In 1832 there belonged to it 296 ships, of the burthen of 46,567 tons. The amount of customs, in 1831, was 1,168,978*l.*, chiefly from duties on West India produce; and there entered its port 2547 vessels, of the burthen of 625,000 tons. It has still the remains of a magnificent cathedral, and the beautiful church of St. Mary Redcliffe, with

many interesting monuments. The old interior of Bristol is ill-built and inconvenient; but the merchants in the new quarters of the city have reared some handsome streets and squares. Bristol has wells, considered very efficacious, especially in consumptive complaints. Visitors chiefly resort to the beautiful village of Clifton, about a mile distant, amid the romantic rocks of St. Vincent. Bristol stands conspicuous for its beneficent institutions, which were actively promoted by Mr. Colston, one of its most distinguished citizens, and in which those for education stand prominent. The charge of dulness, which it seems was once preferred against this city, seems now completely wiped off; since, in science, Dr. Beddoes, a native of Shiftnall in Salop, established here that institution which called forth the talents of his pupil Sir Humphry Davy, originally from Penzance; and in poetry, Chatterton, Southey, and Coleridge were natives of Bristol.

1875. *Bath* (*fig. 175.*), a gayer scene, next attracts our notice. Its name implies the

BATH.

circumstance to which from the earliest ages it has owed its importance. The Romans, passionately attached to the species of luxury which its hot springs afforded, made it one of their principal stations, and built splendid baths, of which the remains have been discovered. Bath, therefore, was always considerable; but it was not till near the middle of the last century, when the taste for watering-places was so much extended, that it became so very distinguished as a scene of fashionable residence. It continued to increase till recently, when its attraction was shared by Cheltenham and some newer places of resort. It became the most beautiful, we may nearly say the only beautiful, city in England. The houses, built of a fine freestone, while those of almost all the other great towns are of brick, have a decidedly superior aspect; and several of the streets, as Great Pulteney Street, the Crescent, the Parades, &c., being not only composed of fine houses, but formed on a regular plan, may vie with the finest in Europe. The city, moreover, rising by a gentle ascent from the Avon, large portions of it may often be seen at once in the most advantageous points of view. The pump-room, the assembly-room, and every structure raised for the sick or the gay, are unequalled in splendour. Bath has a Gothic cathedral, one of the latest built, and on a small scale, but the most highly ornamented in the kingdom; the chief beauty is in the west front.

1876. *Other venerable and interesting cities are found in Somersetshire.* Wells is chiefly distinguished by

WELLS CATHEDRAL.

a cathedral (*fig. 176.*), which ranks with the finest in England. Various styles prevail; but the western front, built in the 13th century by bishop Jocelyn, is one of the most splendid specimens existing of the light and highly ornamented Gothic. In the interior, a chapel dedicated to the Virgin is much admired; the rest is Saxon, and heavy. The place itself is small, but neat and handsome. About two miles distant is Wookey Hole, a natural cavern, one of the greatest of English curiosities. The aperture, at first, merely allows one man to pass; but it soon opens into a succession of large apartments, filled with spars, concretions, petrifications of the most fantastic forms, to which the people of the county assign strange names and

similitudes. A subterraneous river prevents farther advance. A few miles distant are Cheddar Cliffs, forming an awful chasm of broken perpendicular rocks, resembling ruined towers and battlements, and penetrated by deep caverns. Glastonbury contains the small remains of the most extensive monastery in the kingdom; which, with its various gardens and offices, covered sixty acres, supported 500 monks, and enjoyed a revenue of 25,000*l*. Even the church attached to it rivalled the greatest of the English cathedrals. Plundered by the reforming avidity of Henry VIII., it was successively demolished; and only a few fragments of extreme beauty are left. Bridgewater and Taunton are both considerable towns of note in history, which carry on some trade and manufactures. Wellington gives a title to the greatest commander of the age, in whose honour a pillar is there erected. Frome is a large and flourishing town, employed in the woollen manufacture; which Shepton Mallet, near it, carries on upon a smaller scale. Ilchester, Bruton, and Castle Cary are pleasantly situated in the fine eastern vales of Somerset. Minehead and Porlock are picturesque watering-places on the Bristol Channel.

1877. *The seats are few*, property in this county being much subdivided. At Burton Pynsent, is a monument to the memory of the late Lord Chatham, to whose family it now belongs. Mr. Miles, at Leigh Court near Bristol, has formed a splendid collection of paintings, including the Altieri Claudes.

1878. *Devonshire* is the most westerly county except one, and, next to Yorkshire, the most extensive, filling the greater part of the space between the Bristol and the English channels. The surface is uniform, without being level. It is traversed by great ridges of hills, low, broad, and flat, which, seen from a height, appear often as one uninterrupted plain; but on minuter inspection are found separated by deep valleys called *coombs*, so walled in by the steep sides of the hills, that they would often appear inaccessible, did not the appearance of culture and habitation prove the contrary. This structure produces many sequestered and romantic sites, of a character peculiar to Devonshire. It renders, however, many of the roads steep and circuitous, and in some places, where they are not carefully made, scarcely passable, unless for a Devonian. The forest of Dartmoor, an extensive district on the west of the county, is of a character peculiarly rugged, broken into fantastic summits, and the valleys chiefly under wood or lying waste. On the other hand, the Vale of Exeter, and what are called the Hams, in the southern districts, are distinguished for fertility, which is rather heightened than injured by the moderate inequalities of the surface. Grain, cattle, sheep, potatoes, excellent cider, are raised according to the situation, and are all generally good. The cattle are of a very superior breed, both for feeding and draught. Mr. Marshall considers the charge of an inordinate self-esteem as established against the Devonians; inspired perhaps by their having preceded central England in civilisation, yet being unwilling to adopt its now improved practices. Much good has, however, been done by an agricultural society established at Exeter. Devonshire does not rank high as a manufacturing county; yet woollens are made to some extent in Exeter and several other places. Fishing is carried on with spirit and success, both in the sea and in the rivers; of which last, the Exe and the Tamar are the principal. The Western Canal, joining the two channels, passes chiefly through Devonshire.

1879. *Exeter*, the capital, is an ancient and pleasantly situated town, near the mouth of the Exe. In consequence of its advantages for education and society, many of the gentry from different parts of the county have made it their residence. Its manufacture and export of serges and kerseys have declined, but are still considerable; the East India Company taking them to the annual value of 400,000*l*. The cathedral holds a high rank among ecclesiastical antiquities. Some part of it is traced to the ninth century; but the greater proportion belongs to the thirteenth and fourteenth. The painted east window, and the bell of 12,500 lbs. weight, the gift of Bishop Courtenay, are particularly noticed. Some modern embellishments have been added.

1880. *Plymouth* is the most important of the towns of Devonshire, and one of the great naval arsenals of Britain. The main and central depôts lie at Portsmouth and on the Thames; but it is important that the fleets should have this exterior station, where they may rendezvous, and receive their final equipment and supplies before leaving the Channel; where also, when exhausted, they may put in and refit. The Plym and the Tamar, at their junction, form an estuary of nearly two miles broad, composing a harbour, or rather a series of harbours, capable of containing 2000 vessels in a state of perfect security. In that of Hamoaze, on the Tamar, 100 sail of the line may be safely moored. Catwater (properly Cadwater, from the rivulet Cad, which flows into it), the port at the mouth of the Plym; and Sutton Pool, immediately adjoining the town; are both excellent and extensive. Plymouth Bay forms also an excellent roadstead, though exposed to the heavy swell which came in from the Atlantic. To remedy this, government undertook that stupendous work the Breakwater, a mole formed by immense stones heaped upon each other, stretching across the entrance, and at a certain distance from either shore (*fig. 177.*). The estimated

177

PLYMOUTH BREAKWATER.

expense was 1,170,000*l*.; and the quantity of stone, 2,000,000 tons. It has completely answered expectation; and, in proportion as it has advanced, has rendered the roadstead more secure. As the approach was also rendered dangerous by the Eddystone rocks, a lighthouse has, after much difficulty and several unsuccessful trials, been erected there by

Mr. Smeaton, sufficiently firm to withstand the furious assaults of the Atlantic waves to which it is exposed. Plymouth is now divided into two nearly equal parts — Plymouth and Plymouth Dock, at the mouth of the Tamar, recently called Devonport, and raised to the dignity of a separate borough. The dock-yard is most superb; 3500 yards in length, and from 1000 to 1600 in breadth. All the establishments connected with it, the ropery, smithy, saw-pits, mast-houses, as also the victualling departments, are on the most extensive scale, yet conducted in the most regular order. Plymouth is not, on the whole, a well-built town: but it contains some handsome edifices; as the government-house; the theatre, chiefly of cast-iron, and said to be the handsomest country theatre in England; the public library, an elegant and classical structure. The charitable institutions are numerous.

1881. *Devonshire has besides a number of small towns*, of from 2000 to 5000 inhabitants. Barnstaple is a sort of capital of North Devon, situated on a rich plain, retaining still a few manufactures, and frequented by some fashionable society. Biddeford is a dirty seaport, with, however, some little trade. Ilfracomb is a decayed seaport, surrounded by some of the wildest and most peculiar scenery in Devon. To the east, between the villages of Coomb Martin and Linton, is the Valley of Stones, a dreary abyss, in which pointed rocks and piles of loose stones present themselves under every wild and rugged aspect. On the southern coast, Dartmouth carries on some foreign trade; while between it and Teignmouth is Torbay, where, sheltered from the heavy gales that blow up the Channel, the British fleet can ride safely at anchor. Teignmouth, Dawlish, Exmouth, and Sidmouth, are agreeable ports, commanding grand views of the sea and the surrounding shores. Tiverton, Honiton, Axminster, South Molton, Tavistock, are neat interior towns with some manufactures, particularly the first, which has also a name in history. Okehampton and Lidford, on the borders of the forest of Dartmoor, are noted for the ruins of castles formerly of great strength.

1882. *Among a number of fine seats*, we must not omit Mount Edgecombe, superbly overlooking a lawn which slopes down to the English channel, and which has been considered, as to situation, the finest villa in England. Powderham Castle, the richly ornamented seat of the Courtenays; Ugbrook, in a beautiful park, where Lord De Clifford has a beautiful library and collection of pictures — are conspicuous objects.

1883. *Cornwall*, the most westerly county of England, is a peninsula of a triangular form, bounded on the east by Devon, and on the other sides by the sea. The hills, although not more lofty than those of Devon, are much more sterile and rocky: they form a bleak central ridge, diminishing in height as it extends westward, and terminating in the rugged and obtuse point called the Land's End. In figure, this county has been said to resemble a cornucopia; a resemblance which well accords with its ancient British name, *Cernyw*, originally signifying a horn, and aptly applied to designate a headland or promontory. The vapours borne from the Atlantic by the prevailing westerly winds, render this, perhaps, the most rainy district of England. The sterility of the hills is increased by the frequent rains that wash down the vegetable soil; but some of the narrow valleys, from the same cause, constantly wear the aspect of smiling fertility. Almost the only lands under cultivation are in those situations, or in others equally sheltered, near the sea-coast. Oats, barley, and especially potatoes, are grown there in abundance; but wheat is imported. In some secluded spots the climate is so genial, that the myrtle and other shrubs peculiar to the south of Europe flourish in the open air. The principal rivers are the Tamar, the Lynker, the Looe, the Fowey, the Camel or Alan, and the Fale; besides which there are numerous streams, and springs of excellent water. The county is seventy-eight miles in length; at the eastern boundary its breadth exceeds forty-three miles, but continually diminishes toward the west: its area is computed at 1327 square miles; and the mines give occupation to more than 16,000 of its inhabitants.

1884. *Cornwall has from the earliest ages been renowned for its mineral products*. They were the objects of a considerable commerce in times when only the western parts of Britain and the Isles of Scilly were obscurely known to the Greeks, under the name of Cassiterides. In the reign of Henry III., the mines, with the Jews who farmed them, were placed by that sovereign at the disposal of his brother Richard earl of Cornwall and king of the Romans, who enjoyed nearly the entire profit of supplying all Europe with tin, as the mining districts of Spain had been brought under subjection of the Moors. In the eleventh year of Edward III., this earldom was constituted a duchy by a charter; which is distinguished as the first ever issued for creating a duke in England. Edward the Black Prince was declared Duke of Cornwall, to hold to himself and his heirs, kings of England, and to their *first-born* sons: at the same time, lands in other counties, as well as in Cornwall, were constituted parts of the duchy; and a grant was made by patent of the stannaries in Cornwall, together with the coinage of tin, and all the issues and profits thence arising; as also the profits and perquisites of the court of stannaries, with certain reservations. The duke of Cornwall has the power of appointing a chancellor, a lord warden, a receiver-general, and other officers for the administration and management of the affairs of the duchy.

1885. *The mineral products of Cornwall* are principally tin and copper; it also yields some lead. These metals occur in the granite chain, extending eastward as far as Dartmoor in Devon; but at present the principal mining district is that between the Land's End and St. Austel. The most celebrated are the tin mines of Palgooth*, about two miles west of that town: in these there are no fewer than fifty shafts, of which twenty or thirty are constantly in use. The principal vein of ore, which is about six feet thick, runs from east to west, and dips to the north with an inclination of about six feet in a fathom. The

* Dr. Maton's Observations on the Western Counties.

ore is of the vitreous kind, but rarely found in crystals; the colour for the most part greyish-brown; the *country* of the ore is a grey killas. About fifty or sixty feet below the surface of this mine, the water that percolates through the different strata begins to form small streams, which would soon overflow the lower part if not constantly carried away. This operation is performed by a stupendous steam-engine, which raises up to the adit, and discharges at each movement a column of water fifty-six fathoms deep and fifteen inches in diameter. Steam power has also been substituted for that of horses in moving the machinery employed for raising, washing, and stamping the ore; after which last operation it is carried to the smelting-house. Tin cannot be sold until it is assayed and stamped with the duchy seal; for which purpose meetings are usually held four times a year. The annual produce is estimated at 20,000 or 25,000 blocks, each block weighing from $2\frac{3}{4}$ to $3\frac{3}{4}$ cwt., and valued on the average at ten guineas. *Grain tin*, which is obtained from stream ore, is deemed superior in value to the common metal, and has been procured to the amount of 2000 or 2400 blocks annually. In some of the stream-works native gold has been occasionally found. The annual produce of copper is about 13,000 tons, estimated at 1,300,000*l*. The lead mines, being considered as not productive, are not much worked, although the ores are understood to be rich in silver. The tanners are in many respects a distinct body of men; they have a court and parliament of their own. The stannary laws, by which the mines and the operations connected with them are regulated, do not appear to have undergone any change since the reign of Charles II.

1886. *The pilchard fishery* affords another source of wealth to Cornwall. The pilchards appear annually in vast shoals about the middle of July; and are taken in large nets of a peculiar form, called *seans*, each sean managed by three boats, containing eighteen men. In productive seasons, nearly 30,000 hogsheads have been brought into the port of Fowey alone. After lying salted in store for six weeks, the fish are packed in hogsheads, so closely that the whole contents, when turned out, appear in a compact state. The oil expressed from them is so considerable in quantity as to have become an article of trade. The principal export of pilchards is to the catholic countries on the shores of the Mediterranean. The average price is from 35*s*. to 42*s*. per hogshead. The total quantity annually exported from the Cornish coast may be worth 50,000*l*., including the receipts for oil. The number of persons employed in this fishery is about 5000.

1887. *The Cornish men*, especially the miners, are a peculiar race, whose origin is said to be Celtic. Their language, now extinct, was reputed to be more harmonious than either the Welsh or the Armoric language of Bretagne. Traces of it are found in the names of ancient towns and castles, as well as in those of rivers and mountains, and in the technical terms relative to the arts of mining, fishing, and husbandry.

1888. *Of the preponderance till now possessed by Cornwall* in the national representation, through the return of 44 members to parliament, a vague notion is entertained by some persons, that it resulted from a state manoeuvre of Charles II. Its real origin indeed is not very ancient, and is ascribed to the large revenue yielded by the duchy to the crown, or to the heir apparent. In the time of Edward I., only the *county*, and the five boroughs of *Launceston*, *Liskeard*, *Truro*, *Bodmin*, and *Helston*, had the right of returning members. In the reign of Edward II., *Lestwithiel* was enfranchised; and it was not until that of Edward VI. that this privilege was extended to *Camelford*, *West Looe*, *Grampound*, *Bossiney*, and *Newport*. In the first year of Queen Mary, *Penryn* was added to the list of boroughs; and about three years afterwards, *St. Ives*. A short time subsequent to the accession of Elizabeth, *Tregony* was enfranchised; in the fifth year of her reign, *St. German's* and *St. Mawes*; in the thirteenth, *East Looe* and *Fowey*; and in the twenty-seventh, *Callington*; by which addition the boroughs were increased to twenty-one. By the Reform Bill thirteen of these — *St. Michael's*, *Bossiney*, *St. Mawes*, *West Looe*, *St. Germain's*, *Newport*, *Camelford*, *East Looe*, *Tregony*, *Callington*, *Saltash*, *Fowey*, *Lostwithiel*, were disfranchised, leaving only seven.

1889. *The towns of Cornwall* are small. *Launceston*, situated on the Tamar, at the very border of Devonshire, extends up the side of a hill, on the summit of which are the remains of a small fortress called *Castle Terrible*, where a vigorous stand was made to sustain the sinking fortunes of Charles I. Its church, built in the reign of Henry VIII., exhibits a specimen of the meretricious finery which disgraced the Gothic architecture of that period. *Truro* is a neat thriving town, the trade of which consists in a considerable export of tin. At *Bodmin*, a place of ancient note, the summer assizes are still held. *Redruth* is a populous town, in the heart of the mining district. *Penryn* flourishes by the pilchard fishery. *Penzance*, near the Land's End, participates in the same source of wealth, and has of late years acquired distinction and prosperity from other causes. The mild salubrity of its air has been found highly beneficial to persons of delicate constitutions, particularly of a consumptive tendency; and those who take up their residence at *Penzance* are agreeably surprised by the lovely scenery in its neighbourhood. Its market is well supplied with excellent provisions, especially fish, at a cheap rate. *Falmouth*, the westernmost of the fine harbours on the Channel, is the principal packet station for Lisbon, the Mediterranean, and the West Indies. Notwithstanding its natural advantages, it dates its importance as a seaport no earlier than the reign of James I., and did not receive its present name until that of Charles II.

SUBJECT. 5. *Wales.*

1890. *Wales* is a territory which, though united to England by early conquest, still retains the title of a separate principality, and possesses a national aspect, and even forms of social existence peculiar to itself. The verdant and extensive plains of western England here give place to the lofty mountain, the deep valley, the roaring torrent, and the frightful precipice. Wales, like Cumberland, is a mountain region, and still more elevated; but it is not a country of lakes. About sixty have, indeed, been numbered: but they are mere lakelets or tarns, rocky basins formed in the acclivity of steep hills; not those smiling expanses, which give a soft grandeur to the Cumbrian scenery. Wales, on the other hand, has rivers and torrents without number, which roll through its mountain valleys, and whose banks, adorned with verdure and cultivation, combine in the most striking manner with the lofty and varied summits which tower above them. Sometimes these streams force their way through deep rocky recesses, the perpendicular sides of which rise to a wonderful height; and occasionally a bridge thrown across from one to the other, over a torrent roaring deep beneath, produces some of the most picturesque and terrific scenes that are to be found in the island. All the loftiest mountains are in North Wales; its valleys are deeper and narrower; and it presents more strikingly all the characteristic features of Welsh scenery. In South Wales, on the contrary, the valleys are broader, more fertile, and fuller of towns and villages; they often even expand into wide plains, still encircled by a mountain boundary. Agriculture, in such a country, labours under many disadvantages, and is carried on too often upon the old system of infield and outfield. The associations, however, now formed for its advancement, the improvement of the roads, and the formation of canals, are beginning to produce happy effects. Manufactures are nearly confined to the comfortable article of flannel, which has been always a fabric of the Welsh, in which they still excel their Yorkshire rivals. It is made in almost every farm-house, and under the various forms of webs, hose, gloves, wigs, and socks. It is to mining, however, that the industry of Wales has been chiefly attracted, by the profusion of mineral wealth which nature has lodged in the bowels of its mountains. Silver is little more than an object of curiosity, though a part of Cardigan once assumed the name of the Welsh Potosi. But the lead of Flint, Caernarvon, and other counties of North Wales, the copper of Anglesey, and, above all, the iron of Glamorgan and other counties in the British Channel, are objects of real and extensive importance. Coal is found almost every where, and is employed either for domestic purposes, or in fusing and refining the metallic ores.

1891. *The Welsh are a Celtic race*, the genuine descendants of the ancient Britons, who, in these mountain recesses, sought refuge from the destroying sword of the Saxons, which so completely dispossessed them of the low country of England. They had entirely shaken off the effeminacy of their ancestors; yet could not resist the overwhelming power of Edward I., who annexed Wales to the English crown. In order to hold it in subjection, however, he was obliged to construct, not only on its frontier, but in its interior, castles of immense extent and strength. These castles now form one of the most striking and characteristic features of Wales, Conway, Caernarvon, and perhaps Caerphilly. Yet they did not prevent formidable insurrections, in one of which Owen Glendower maintained himself for years as an independent prince. Within the last 300 years, the Welsh have been as peaceable as any other subjects of the empire. Like the Highlanders, they have retained, of their feudal habits, only venial and amiable failings. Among these is national pride, through which the genuine Cambrian holds his country and his nation superior to all others; and regards the *Sasna*, or Saxon, as a lower race of yesterday. With this is connected, in a high degree, the pride of pedigree; even the humblest Welshman tracing his origin far above any lowland genealogy. Strong ties of friendship subsist between the landowners and their tenants: manifested, on one side, by indulgence and protecting kindness; on the other, by a profound veneration for the representatives of the ancient chiefs of their race. The Welsh have many superstitions, mixed with much genuine religious feeling. They are hardy, active, lively, hospitable, kind-hearted; only a little hot and quarrelsome. Their English neighbours complain that they have not yet attained that pitch of industry and cleanliness in which the former place their pride.

1892. *Wales*, as we have already observed, is divided into North and South; of which the former contains, on the greatest scale, all that is most distinctive in the character of the country and people.

1893. *North Wales* comprises the counties of *Caernarvon*, *Merioneth*, *Montgomery*, *Denbigh*, and *Flint*, with the island of *Anglesey*. The whole might be comprised within the limits of a very large English county. The characteristic feature of this division consists in the very elevated chains of mountains which cross it from north to south, facing the Irish Channel. The chief or chief is Snowdon, which raises its head to the height of 3700 feet; yet it is only the most elevated of a crowd of summits, called the Snowdonia (*fig. 178.*), many of which rear peaks almost as high. They cover a great part of the county of *Caernarvon*, at the northern part of which they present to the Bay of Beaumaris the lofty steep

of Penmanmawr, whose broken fragments threaten to bury him who travels the difficult

SNOWDON.

path which has been formed along its almost perpendicular sides. Snowdonia encloses in its rocky basins many clear little lakes, full of delicate fish, of which the principal is Bala, which gives rise to the Dee. Merioneth is chiefly covered with inferior, but still very lofty and rugged mountains, bearing the names of Ferwyn, Arren, and Arrenig; till, towards the southern extremity, they tower into Cader Idris, the second summit of Wales. It is every where steep, craggy, and precipitous, piercing to

the sky by three lofty pinnacles. Lastly, in the heart of Montgomery, towers the huge mass of Plinlimmon, with a crowd of attendant mountains.

1894. *The vales* which intervene between these heights diversify bleak and barren regions, otherwise calculated to inspire only impressions of dreary sublimity. The most extensive is that of Clwyd, in the county of Denbigh, where the mountain chains gradually sink. It is about twenty miles in length, and four or five of average breadth; and presents a more brilliant picture of fertility, heightened, doubtless, by contrast, than almost any other spot in the island. The narrower vales, however, present more of picturesque beauty, particularly that of Llangollen, where the Dee, winding through cultivated and pastoral scenes, overhung by high rocks and cliffs, presents at every step a varying landscape. Even in the heart of Snowdonia, the little verdant and wooded vale of Festiniog, with numerous streams uniting at the bottom into a little river, forms a scene of almost unrivalled beauty. The island of Anglesey is generally level, and its scenery presents few striking features, except the rocks of its western shore. It has happened, fortunately for the improvement of this formidable range of territory, that it lies on the highway from London towards Dublin; and with the view of facilitating the intercourse between the kingdoms, government, at the national expense, has formed one of the finest roads in the world; among the principal features of which is the stupendous iron suspension-bridge, formed across the arm of the

179

CAERNARVON CASTLE.

sea, called the Menai Channel. The chief centre of the flannel manufacture is in Montgomery and Merioneth. The lead mines of Holywell and the copper mines of Anglesey possess an importance scarcely inferior to those of South Wales.

1895. *Caernarvonshire* includes the grandest and most characteristic features of North Wales. The capital, Caernarvon, is a handsome, well-built town, and, for its situation, considerable. Its chief ornament is the castle, a mighty and stately edifice (*fig. 179.*), built by Edward I. to curb the spirit of the newly subdued Welsh, and also to

180

CONWAY CASTLE.

soothe them by the circumstance of his queen, Elinor, giving birth within its walls to the heir of the monarchy. It encloses an area of two acres and a half; the towers are of stupendous magnitude, and crowned by light and beautiful turrets. To the south of Caernarvon is the steep ascent of Snowdon, whence a view of astonishing extent is commanded; though only to be seen in those fortunate days when the veil of mist, which usually wraps it, has been dissipated. On its declivity is the wild and rocky lake of Llanbieris, with the ruined castle of Dolbadern overhanging its banks. Nearly at the opposite extremity of the county is Conway; rather a poor town, but containing the walls of a still more magnificent castle (*fig. 180.*), also erected by Edward I. The interior is in a state of total ruin; but the view, from a little distance, of its eight mighty towers, ranging along the summit of a lofty rock, which overlooks the broad surface of the Bay

of Beaumaris, presents an image of grandeur which scarcely any other castellated structure in the kingdom can rival. About midway between these two castled sites is Bangor, a pleasant little town, viewing on one side the awful grandeur of Snowdonia, and on the other the fine expanse of Beaumaris Bay. Bangor lies on the high road to Holyhead and Dublin; and about two miles distant is the suspension bridge over the Menai; already mentioned. Here, and at Penryn, is a great shipment of slates, brought from the steep sides of the neighbouring mountains.

1896. *Merioneth*, though it cannot boast a summit equal to Snowdon, displays scenery still more uniformly wild and rugged. It has a few large villages, each enclosed by a circuit of lofty and almost inaccessible mountains. Corwen is a pleasant little town, on the high road, and on the eastern border. Bala is supported by a small manufacture of knit

181

CADER IDRIS.

gloves and stockings, and by the vicinity of the largest of the little lakes of Wales, which has clear water and abounds in fish. Dolgelly, about midway between Snowdon and Cader Idris (*fig. 181.*), is seated in the very heart of all the grandest scenery of Wales. To the north are a succession of beautiful cascades, particularly those of the Mouddach, the vale of Festiniog, with the pleasing village of Maentwrog at its foot. Pont Aberglasslyn affords one of the grandest examples of the bridge scenery of Wales. On the south arise the steeps of Cader Idris, on the opposite side of which is the little maritime town of Towyn. On the coast, the castle of Harlech,

built also by Edward, bears marks of great strength.

1897. *Montgomery*, though its centre is occupied by the "huge Plinlimmon," whence branches shoot out in every direction, giving rise to the Severn and the Wye, is yet, on the whole, of a milder aspect. It has some fine valleys, particularly that of the Severn; and many of its hills are green to the summit. The manufacture of flannel is carried on with considerable spirit. The town of Montgomery is small, pleasantly situated on the declivity of a hill, crowned with the ruins of a once noble castle. Welshpool is an ill-built straggling town, but has a great market for flannels; and communicates by a canal with Chester and Ellesmere.

1898. *In proceeding to Denbigh and Flint*, which border on the Irish Sea, we quit the thoroughly alpine region of North Wales, and come to broader valleys, and hills gradually diminishing down to the level plain of western England. Denbigh, a pleasant, ancient, little town, is crowned by a castle, seated on a high rock, looking down to the vale of Clwyd, proverbial for its smiling fertility. Farther down the vale is the thriving little town of Ruthin. In the valley of the Dee, and on the confines of Cheshire, to which it almost belongs, is the considerable town of Wrexham, noted for its fairs, in which Welsh flannel is the staple commodity. But the chief ornament of Denbigh is Llangollen Vale, on the upper Dee, where the mixture of culture and wildness produces the most striking variety of scenery. Among its leading features are the ruined castle of Dinas Bran, crowning the steep summit of one of the principal hills; and the remains of the Abbey of Valle Crucis. This last is situated in a valley connected with that of Llangollen, enclosed by lofty mountains verdant to the summit, and sprinkled with trees. The edifice has been in the simplest style of Saxon architecture; but the situation, the fragments that lie strewn around, and the trees and shrubs which grow, even in its interior, render it one of the most picturesque spots in England. Chirk, an agreeable village, has near it a castle, one of the most perfect of the many with which Wales is adorned. Near it also is the very fine aqueduct of Pont-y-Cysilte, by which Mr. Telford has conducted the Ellesmere Canal over the Dee, resting on 18 piers, 1007 feet in length, and 126 feet above the level of the river.

1899. *Flint* is a small county, diversified by rocky hills of lower elevation, but rich in lead and other mineral stores. The county town of Flint, and its castle, have entirely lost the importance they possessed when they were the prison of Richard II.; and the glory of Caerwys, the ancient scene of musical and poetical contest, has entirely passed away. The chief interest of the county consists in the industrious town of Holywell, which, besides its extensive lead mine, carries on works in brass and copper, and even some cotton fabrics. Here the sacred well of St. Winifrede, from which it derives its name, is beneficially applied to the purposes of industry. Hawarden flourishes by a foundery for ordnance, and by extensive works in earthenware, carried on in the neighbouring hill of Bulkley. The lead mine of Llan-y-Pander is the most extensive in the kingdom, and employs four vast steam-engines in clearing off the water. Mold is a pretty large town, in the centre of a rich plain of the same name. St. Asaph attracts notice by its small but very neat cathedral.

1900. *The Island of Anglesey* is now considered a province of North Wales, though, instead of a mountainous character, it presents, generally, that of a naked and gloomy flat. It is said to have been anciently the central seat of druidical superstition, still attested by the *cromlechs*, or large, flat, stone tables supported by rude pillars, which are more numerous here than in any other part of Britain. Its importance has rested almost entirely upon its mineral treasures, particularly those extracted from the bosom of the Paris mountain, near Amlwch. This mountain consisted of one entire mass of copper, the greater part of which has been dug out of its excavated sides. These are now laid open to the eye of the spectator, who, standing on the edge, sees an awful range of huge caverns, profound hollows, stupendous arches, and enormous masses of rock; and amid all these, the miners plying their singular and perilous trade. The ore contains about 25 per cent. of metal; and the entire produce has amounted to nearly 80,000 tons; but of late the mine

182

HOLYHEAD.

has become very unproductive, and the annual amount is only from 750 to 950 tons. Beaumaris, which ranks as the capital, is a neat little town, commanding from Baron Hill, in its immediate vicinity, a most splendid view of the mountain scenery of North Wales. Much more importance attaches to Holyhead, now the main point of communication between England and Ireland. To render it such, government has constructed a noble road from London, across the most rugged part of North Wales, and also made an admirable harbour. The neighbouring coast is very bold, and the promontory, called the Head (*fig. 182.*), consists of immense masses of precipitous rocks, hollowed into deep caverns, and echoing with the clang of numberless sea-fowl. The town itself has been rapidly extended and improved.

1901. *The seats in North Wales*, though not extremely numerous, are yet more than we can well recount. Bacon Hill, in Anglesey, has been mentioned for its beautiful views. Plas Newydd and Penrhyn Castle, finely situated on the Menai Strait, are both castellated mansions, modernised and highly ornamented. Wynnstay Park, near Llangollen, is the ancient domain of the Wynns. In Flintshire are Hawarden Castle, surrounded by extensive woods, and Mostyn Hall, near Holywell, presenting varied specimens of the different styles of architecture successively prevalent from the reign of Henry VI. Near Montgomery is Powis Castle, which dates from the twelfth century, and was long one of the proudest fortresses in Wales: it is still a superb modern seat; though the principal residence of the Powis family has been transferred to Walcot House, in Shropshire.

1902. *South Wales* comprises the counties of Radnor, Cardigan, Brecknock, Caermarthen, Pembroke, and Glamorgan. Its general character has been already noticed in comparison with that of North Wales. Though its features are not on so vast a scale, it presents scenery equally romantic, mingled with a greater degree of softness and cultivation; and its agricultural and mining products are of considerably greater value.

1903. *Radnor*, the first county that presents itself as we proceed from the north, is one of the least considerable. It is composed of bleak ranges of mountains, in some parts almost impassable. The Wye, in traversing it, forms a valley in which there is some cultivation; but the greater part is only fitted to afford pasture for sheep, the wool of which is valuable. New Radnor, once a fortified city, is dwindled into a village. Presteign, though not meriting any higher title, is neater and more flourishing.

1904. *Cardigan* is a much more interesting county. Its mountains, though not of stupendous elevation, are varied, broken, interspersed with deep valleys and ravines, through which a number of small rivers dash towards the bay of Cardigan. The county thus includes some of the boldest features of Welsh scenery. The domain of Hafod, in particular, has been covered with extensive plantations, so happily disposed as to render it almost a scene of enchantment. At a few miles' distance is an object which, from its sublime and terrific aspect, is called "the Devil's Bridge;" an arch thrown over a deep and narrow rocky chasm, overgrown with wood, at the bottom of which rolls the Mynach, after rushing down three lofty cascades; forming altogether the grandest scene of the kind in the kingdom. The lead mines of Cardiganshire are very extensive, though the want of fuel has caused the working of many of them to be discontinued. Cardigan is a small old town, which carries on a considerable coasting trade, having nearly 300 small vessels belonging to it. There is great resort to Aberystwyth, an agreeable bathing place, which commands an extensive view of the range of the northern mountains. Its trade is also considerable, extending even to Bristol and Liverpool.

1905. *Brecon*, or *Brecknock*, in the interior from Cardigan, is, like the rest of Wales, mountainous and rugged, but has some fertile lands in the valleys of the Uske and the Wye. There, chiefly through the exertions of a county society, agriculture is conducted in a more skilful manner than in most other parts of Wales. Brecon is an ancient town on the Uske, amid lofty mountains, and surrounded by delightful walks. Like every other place in Wales, it has the remains of a castle, which was once strong, and held by Buckingham, the favourite and afterwards the victim of Richard III.

1906. *Caermarthen* is a more favoured province; and though it includes an ample proportion of bleak and barren hills, these are intermixed with large fertile valleys, particularly that of the Towey, which traverses the whole extent of the county. It thus produces, not wheat indeed, but oats and barley, of which quantities are exported to Bristol. There are also abundance of coal, and some iron works on the Glamorgan border. The capital, situated on the Towey, which admits to it vessels of 300 tons, is one of the most flourishing and best built towns in Wales. Its antiquities are almost effaced; but it has a handsome town hall and modern church.

1907. *Pembroke*, the most remote extremity of Wales, consists of a peninsula branching out between the Irish and Bristol channels. The great range of the Welsh mountains here terminates; and, with the exception of a few detached summits, the country presents merely an undulating surface, rising at most to elevations of 200 or 300 feet. Hence, notwithstanding a rude and antiquated system of agriculture, it is made to yield considerable quantities of oats, of barley, and even of wheat. Its breed of cattle is also in high repute. Its wide and indented coasts contain some of the finest harbours in Britain; yet it does not excel either in trade or manufactures. The mineral field also here terminates; and the coal that occurs is of inferior quality. Two Roman roads, in different directions, cross this county, which is also very rich both in druidical and feudal monuments. The ancient city of Pembroke is strikingly situated on an almost insulated neck of land on the bay of Milford Haven, the highest part of which presents the vast remains of its castle, one of the most magnificent structures of which Wales or England could boast. It was built in 1092, upon the site of a more ancient British fort, and was considered almost impregnable till, after an obstinate resistance, it was reduced by Oliver Cromwell. The town contains some churches, ancient, but not elegant. The large bay composing Milford Haven is now generally allowed to form the most capacious and secure harbour in Britain. Hence government have been induced, at the new towns of Milford and Haberstone, on its northern shore, to form dockyards and establish packets for the south of Ireland. The largest town of Pembroke, however, is Haverfordwest, situated on a small river which falls into St. Bride's Bay, and admits vessels of 100 tons. It continues to support itself by some trade and industry. Fishguard is a fishing town on a very fine bay of the same name. St. David's, the ecclesiastical capital of South Wales, is now only a large dirty village, adorned, however, with venerable ancient structures. Narberth is a neat town with some striking remains of a castle. Pembroke is crowded with castles, among which stands, in solitary grandeur, Kilgarran, on the borders of Cardigan, where its massy towers and fragments present a most imposing spectacle. It commands also a fine view along the course of the Towey. Carew Castle, near a small village of the same name, shows, likewise, some magnificent remains.

1908. *Glamorgan* is the finest county in South Wales, and, as to wealth, superior to any other in the principality. Its coast, along the Bristol Channel, and for some miles inland, is level, and fertile in the extreme. Thence the ground rises into hills of continually increasing elevation, till, on the frontier, they rise to the height of upwards of 2000 feet, and unite with the Brecon chains. From these heights descend numerous streams, which, in their progress to the sea, produce all the varieties of ravines, wooded vales, falls, and cataracts; which, with the beauty of the plains below, and the fine views over the Bristol Channel, render Glamorgan equal in picturesque beauty to any other county in Wales. Notwithstanding, also, too close an adherence to the old system of exhausting the ground, and leaving it to recruit, and the employment of huge and useless teams of oxen, the crops of every description of grain are ample; and there are good breeds both of cattle and sheep. But all these objects are trifling, when compared with the mineral treasures of Glamorgan. It forms the centre of a vast field of coal and iron, from which branches extend into the neighbouring counties. Since it was found that iron could be smelted with coke, the working of this metal has prodigiously increased, and the town of Merthyr Tydvil, near which it is most abundant, has grown from a mere village to be the most populous place in all Wales. In consequence also of the abundance of fuel, the copper ore dug out in Anglesey, Cornwall, and Ireland, is brought hither to be smelted and refined. The plating of iron with tin is also an extensive occupation. The iron is reduced by immense rollers to the requisite thinness, and is then cut by enormous scissors into plates, which afterwards require little more than simple immersion into the smelted tin. The coal, besides its essential use in these various works, is in itself a most extensive object of exportation, amounting in some years to 300,000 tons. The rivers of Glamorgan are very imperfectly navigable; but this defect has been supplied by industry. From Neath, Cardiff, and Swansea, canals reach far into the interior; and their benefits being extended by railways, a channel has been opened for conveying to the sea the produce even of the most interior mines. Cardiff ranks as the county town, but is now much surpassed by others. Yet it carries on a considerable trade; having a commodious harbour, and being

connected by a skilfully conducted canal with the interior works at Merthyr Tydvil, the produce of which it exports, as well as that of a large tin-plate manufactory in its neighbourhood. It is now, however, much surpassed by Swansea, which has risen to its present importance by immense works in iron and copper, and by the exportation of coal; which is furnished in such abundance, that a large vessel may enter at one tide and go out loaded at the next. Its pleasant situation on a fine bay has also made it an extensive resort for sea-bathing, and led to the erection of many elegant buildings. Swansea has thus risen into a sort of capital of South Wales; yet it is not so large as Merthyr Tydvil has been rendered by the extensive iron works in and round it. There are near it seventeen furnaces, in one of which 11,000 tons of pig iron and 12,000 tons of bar iron are produced annually. Neath, on a river of the same name, flourishes by the ordinary staples of the county. The scenery on the upper Neath, and particularly on its tributaries the Felddta and Hepste, is extremely romantic. Caerphilly, a thriving little town, with some manufactures, deserves notice chiefly from the remains of its immense castle (*fig. 183.*), which present a most stupendous scene of ruins. It is stated to

CAERPHILLY CASTLE.

have been a mile and a quarter in circumference, and capable of containing a garrison of 20,000 men. The great hall is ornamented in a style which displays considerable architectural skill. Amid various conjectures regarding its origin, the most probable seems that of Mr. Warner, who ascribes it to Edward I. We must not forget Llandaff, the only nominal city in the county, but now only a village, the seat of the least richly endowed bishopric in Wales. The cathedral, however, is a fine ruin.

1909. *Elegant villas abound in many parts of South Wales*, but there are few mansions of the first class. Foremost stands Hafod, already noticed as one of the prominent features of Cardigan; and the mansion entirely corresponds to the surrounding scenery. Margham, in Glamorgan, is not only a handsome edifice, but encloses a sort of cabinet of curiosities; a fine conservatory, specimens of statuary, and models of ancient edifices. We may add Dunraven Castle, erected by Mr. Wyndham, on the supposed site of that of Caractacus; and Knoll, whose highly ornamented grounds have been lately neglected.

1910. *The smaller islands attached to England*, being too few and unimportant to stand by themselves, are, for want of any more appropriate place, attached to this subsection.

1911. *Man* (the Mona of Cæsar), thirty miles in length by twelve in breadth, is nearly equidistant from each of the three kingdoms; having opposite to it Cumberland on the east, Galloway on the north, and the Irish county of Down on the west. It comprises a considerable extent of level territory; but rises in the interior into high mountains, among which Snowfell, nearly 2000 feet high, stands conspicuous. Many parts of the coast are very rocky, particularly the Calf, a small appendent island at its southern point, fenced round by gloomy caverns and stupendous rocks, against which large vessels have been dashed to pieces. Its caves and precipices are tenanted by a great variety of sea-birds, whose shrill discordant notes increase the wildness of the scenery. Man ranked long as an independent sovereignty, held by the Earls of Derby, and is celebrated for the gallant and ill-requited defence made by the countess of that name for Charles I. It descended afterwards to the Duke of Athol, from whom the sovereignty was purchased, in 1765, by the British government, with a view to the prevention of smuggling, and to the establishment of a free trade. The coasts of Man are generally susceptible of culture, and are much enriched by the quantity of sea-weed thrown upon them; which, with late improvements in agriculture, enable it to produce large crops of barley and other grain; and there is a great exportation of cattle and butter. The herring-fishery is now much decayed. The natives are shown to be a Celtic race by their language, which bears a close affinity to the Welsh and Gaelic.

1912. *Castletown*, the capital and seat of the courts, is the neatest town in the island; and in its centre, Castle Rushen, the ancient palace of the kings of Man, rears its gloomy and majestic brow. Douglas, however, as being the spot in which the whole trade circulates, is now of superior importance, and has attracted a great number of English settlers. Peel and Ramsay are both much decayed; but the former still presents the venerable ruins of its castle, once deemed impregnable.

1913. *Scilly* is the name given to a group of islands, or rather islets, situated at some distance from the western extremity of Cornwall. They were celebrated in antiquity, under the appellation of Cassiterides, or the Islands of Tin; under which, however, Cornwall, and sometimes even the whole British Isles, were confessedly included. At present they are only tenanted by 2000 poor inhabitants, who raise a little grain, but depend chiefly upon fishing, pilotage, and the making of kelp. St. Mary, the largest town, has a population of 700 inhabitants, and is defended by a small garrison; while on Sampson, the smallest place, there resides only one family.

1914. *Jersey, Guernsey, and Alderney, with Sark*, form a group naturally French, and originally part of the patrimony of the Norman kings, which the naval superiority of England has enabled her to retain. They enjoy certain privileges and immunities, founded on this distinction, as laid down by Coke, that, "though parcel of the dominion of the crown of England, they are not, nor ever were, parcel of the realm of England." The climate is mild and agreeable, and the soil generally fertile. *Jersey*, the finest of the group,

is beautifully diversified with hill and dale, and is so abundant in orchards, that cider forms the chief object of exportation. These islands, especially Jersey, flourished remarkably during the war, from the naval depôts and fortifications formed upon them, and from the favourable stations which they afforded for privateering. Hence St. Helier, the capital of Jersey, was converted from a mere village to a handsome and agreeable town.

CHAP. III.

SCOTLAND.

1915. *The place which Scotland holds as part of Great Britain, has already been exhibited in the introduction to the chapter on England. It is now time to describe in detail this important, though secondary, member of the empire.*

SECT. I. *Geographical Outline.*

1916. *Scotland is bounded on the south by England, from which it is separated by a line drawn along the Tweed, the Cheviot Hills, and thence to the Solway Frith. Its south-west corner faces the coast of Ireland. On every other side it is bounded by vast and stormy seas;*

MULL OF GALLOWAY.

184

the Atlantic and the Northern oceans, which extend to America, Greenland, and the Pole. The length of Scotland between north and south, from the Mull of Galloway (*fig. 184.*), in about $54^{\circ} 40'$ to Dunnet Head, Caithness, in $58^{\circ} 40'$, comprises four degrees of latitude, or 280 miles. The greatest breadth, if taken from Buchan-Ness, to a point on the opposite shore of Inverness, is nearly four degrees of longitude, which, at this distance from the equator, make only 130 miles. This breadth varies little in the large interval between the friths of Forth and Moray; but to the south of the former, the average breadth

scarcely exceeds 100, and to the north of the Moray Frith, 40 or 50 miles. The entire extent of Scotland is estimated in the agricultural reports at 29,600 square miles.

1917. *Scotland, in its general outline, consists of two great and perfectly distinct parts: the Lowlands and the Highlands. The former comprehends all Scotland south of the friths of Forth and Clyde; for the pastoral hills of the southern and western borders, less elevated than the northern mountains, and inhabited by a different race, are not considered as forming any tie between these and the Highlands properly so called. Immediately north of the Clyde, the highland ranges begin to tower in endless succession; but on the east coast, the Lowlands extend beyond the Forth, and northward through the counties of Fife, Forfar, Kincardine, and Aberdeen; though these last are closely encroached upon by the mountain territory. The lowland district also extends round the northern promontory of Aberdeen, and along the borders of the Moray Frith, which contain as level tracts of territory, and enjoy as mild a climate, as any part of Scotland. This level tract does not comprehend quite the half of the country; nor does it any where exhibit those almost boundless plains which characterise the southern part of the island. Even the Lothians, and still more the western provinces, are hemmed in by low ridges of bleak table-lands, covered, in a great measure, with heath and moss. The arable lands are almost solely comprised in broad flat valleys, chiefly along the friths, called *straths* or *carses*. Several of these are much famed for fertility, a blessing but partially bestowed even on the best districts of Scotland.*

1918. *The Highlands, which comprise the whole west and centre of northern Scotland, form a region of very bleak and rugged aspect. A chain of long and lofty ridges extends from south-west to north-east, not reaching, however, the German Ocean or the Moray Frith, but leaving between them the level interval of the northern lowland. These mountains usually dip, almost perpendicularly, into the lakes and seas on which they border; and even the interior valleys are on so high a level that in this climate they admit only in scattered patches the culture of the coarser kinds of grain, particularly oats and bigg. These mountains, particularly the great Grampian barrier, which extends across from Ben Lomond to Blair-Athol, lock in closely with each other, and can be entered only by formidable and easily defended passes. The consequence has been, that they have preserved within their recesses a primitive people, who, in dress, language, and the whole train of their social*

ideas, differ essentially from the Lowlanders, and have retained antique and striking characteristics, both physical and moral, that are obliterated in almost every other part of Great Britain.

1919. *Another very usual though somewhat vague distinction* is into the north and south of Scotland, separated by the friths of Tay and Clyde. The northern lowlands, particularly Aberdeen and Moray, though they are highland neither in aspect nor population, are yet, in both respects, considerably dissimilar to the southern lowlands.

1920. *The Isles* may be considered as comprising the remaining third part of Scotland. On the east, indeed, and even on great part of the south-west coast, only a few bold and naked rocks rise perpendicularly from the ocean. But the western highlands are bordered by the Hebrides, an extensive range of large islands, some of which, Skye, Mull, Jura, are separated from the continent by such narrow channels, that they may almost be considered as forming part of it. Again, the northern extremity of Scotland is prolonged by the two ranges of the Orkney and Shetland islands, in a continuous line with each other, but at some distance. These islands are not highland; they are rocky and bare, exposed to excessive moisture and the perpetual storms of the Atlantic. The population is neither English nor Celtic: it bears, in language and features, the marks of a Scandinavian origin; dating from the period when the piratical rovers of the north made extensive inroads on the western states of Europe.

1921. *Among the Scottish mountains*, the most considerable are the Grampians, a name which is given very generally to all those which cover the surface of the Highlands, but applied more particularly to the chain running across the counties of Perth and Argyle, and comprising Ben Lomond, Ben Ledi, Ben More, Ben Lawers, and others of that elevated ridge which directly face the low country of Stirling and Perth. Several of these approach, and even exceed, the altitude of 4000 feet. Ben Nevis rises to the height of 4315 feet. On the borders of Inverness and Ross-shire, Ben Wyvis, Mealfourvounie,

and some others, are of nearly equal elevation. The south of Scotland is also very hilly; but its heights are seldom more than 2000 feet, green and pastoral. The most remarkable are the boundary chain of the Cheviot, celebrated in the annals of early feud, hunting, and border warfare. The Lowthers, a steep high ridge, including valuable lead mines; the pastoral hills of Ettrick and Yarrow; Criffel and Cairnsmuir, in Galloway, form important objects: the lower ranges of the Pentland and Lammermoor border the Lothians.

1922. *The rivers of Scotland* are not so much distinguished for their length or magnitude, as for the pastoral scenery through which they wind their early course, and for the magnificent estuaries which they form at their junction with the sea.

1923. *The Forth* derives from this last circumstance a higher distinction than the others. It rises near the foot of Ben Lomond, flows due west towards Stirling, near which it is swelled by the larger stream of the Teith; whence, after many windings through the beautiful plain overlooked by Stirling castle, it opens into the great frith on which the capital of Scotland is situated.

1924. *The Clyde* has a course marked by still more striking objects. It rises from a hill in Lanarkshire, on the borders of Dumfries-shire; flows for a considerable space through a wild pastoral valley; then winding near Tinto, it descends, by a succession of most picturesque cascades, into the lower region of Lanarkshire. After passing through a tract which may be denominated the garden of Scotland, and adjoining to the proud walls of Hamilton and Bothwell, it enters Glasgow; then, totally changing its pastoral character, it becomes a broad stream, and the channel of a most extensive commerce. In its lower course, it expands into a winding frith, not so broad as the Forth, but the scene of a much more active trade. Here also its shores are rendered highly picturesque by the proud castle of Dumbarton, the beautiful coast of Bute, and the lofty heights of Arran and Argyle.

1925. *The Tweed* rises from the same chain as the Clyde, and pursues, for some time, a parallel course, separated only by the high ridge of Culter Fell. It then turns eastward, and waters the most beautiful and classic of the pastoral districts of Scotland, in whose verse Tweed is the favourite name. Of similar fame are its tributaries, the Yarrow, the Gala, the Teviot; swelled by whose waters it rolls, a broad stream, by Melrose and Kelso; and on reaching Berwick affords a capacious harbour for the trade of that port.

1926. *The Tay* rises in the central Highlands, out of the lake of the same name, encompassed by some of the loftiest of the Grampians. It early receives the mountain streams of the Lyon, the Tummel, the Bran; and, after sweeping under the picturesque and wooded hills of Dunkeld, descends into the lowlands of Perthshire. Having winded beautifully round the city of Perth, it expands into the Frith of Tay, on the northern shore of which swells the luxuriant tract called the Carse of Gowrie. Finally, the Tay forms the harbour of Dundee, and becomes the channel through which the trade of that thriving place and the interior districts is carried on.

1927. *The Spey*, though last in rank, has a longer course than any other; but, rising in the midst of the Perthshire highlands, and rolling northward through the wild recesses of Athol and Braemar, its line is comparatively obscure, and seldom visited even by the admirers of mountain scenery. Its rude banks are bordered, however, by the extensive fir woods of Glenmore and Strathspey, the timber of which is floated down to the sea at Garmouth.

1928. *The other rivers of Scotland* are numerous, but of subordinate rank; the Dee of Aberdeen, the Esk of Montrose, the Nith and Annan of Dumfries, the Ayr and Irvine of Ayr. There are inferior streams of all gradations; every mountain valley has its "water;" and almost every hill sends down its rivulet or "burn."

1929. *Lochs* form another most characteristic feature of Scotland. The term does not exactly coincide with lake; for many lochs are long arms of the sea, running up into the heart of the mountains, and enclosed by them in the manner of lakes. Among these Lochs Lomond is pre-eminent, and is justly held as the pride of Scotland. The traveller admires its vast expanse, its gay and numerous islands, its wooded promontories and bays, and the high mountain barrier at its head. Loch Katrine, in a smaller compass, presents a singular combination of magical and romantic beauty. Loch Tay, enclosed by the loftiest of the Grampians, presents alpine scenery on the grandest scale; while at Inverary, Loch Fyne unites the pomp of art with that of nature. The long chain of Lochs Linnhe, Lochy, and Ness, stretching diagonally across Scotland, comprises much fine scenery, and has afforded facilities for making a navigable communication between the German and Atlantic oceans. Lochs Broom, Maree, Moidart, and others, deeply indent the western coast, and are in various places enclosed by the remains of large forests; their remote situation, however, renders them not generally known, even to Scotsmen, though they have lately become the seat of extensive herring-fisheries.

SECT. II. *Natural Geography.*

1930. This section will contain Geology only, as the Botany and Zoology of Scotland were described along with that of Great Britain in general, under the head of England.

SUBJECT. 1. *Geology of Scotland.*

1931. *Scotland may be divided geologically into the following great districts:—1. Southern; 2. Middle; 3. Northern; 4. Insular.*

1932. (1.) *Southern division.* This division includes that part of the country bounded on the south by the northern frontier of England; on the north and west, by the comparatively flat country between the Forth and the Clyde; and on the east by the sea. It is traversed from St. Abb's Head on the east coast to Portpatrick on the west coast by a high land, named the *great southern high land of Scotland*, in which are situated the highest mountains in this division of Scotland. This lofty range sends out branches in different directions, many of which reach the sea-coast, while others terminate in the lower and flatter parts of the country that lies around them. The principal rivers of the south of Scotland rise from this high land, as the Tweed, which flows towards the east; the Clyde, towards the north-west; the rivers of Ayrshire, that flow towards the west; those of Dumfries-shire, towards the south; and the rivers of the Lothians, towards the north. Although thus abundantly supplied with rivers, the southern division contains but few lakes, in this respect forming a striking contrast with the middle and northern divisions. The only lakes worthy of being named are Loch Ken in Galloway, and St. Mary's Loch and the Loch of the Lows in Selkirkshire. Springs are sufficiently numerous; but their nature and chemical history have not hitherto engaged much of the attention of observers.

1933. *In this division of Scotland rocks of the primitive class are wanting; but transition, secondary, and alluvial formations abound.* The mountainous regions are composed of transition rocks, while the lower and flatter consist principally of secondary and alluvial formations.

1934. I. *Transition rocks.* The predominating rocks of the Neptunian class are greywacke, with subordinate beds of clay slate, flinty slate, and transition limestone; the Plutonian species are granite, syenite, porphyry, serpentine, and trap. The great southern high land, with many of its branches, is principally composed of these rocks, of which by far the most abundant is the greywacke; all the others, from their small quantity, occurring in a subordinate manner. The principal lead-mines in Scotland, those of Leadhills and Wanlockhead, are situated in the greywacke. They have been worked from an early period, and during a long course of years have yielded to the proprietors a very rich return. Of late years, owing to the disturbed state of the world, their prosperity has been interrupted. Copper ores have been raised in Galloway, but not in considerable quantity; and the same may be said of the sulphuret of antimony, formerly mined at Glendinning in Dumfries-shire.

1935. II. *Secondary rocks.* Scotland, as already remarked, is distinguished from England by the smaller number of its secondary formations, and their more limited distribution. The southern division of Scotland, in comparison of its magnitude, contains a greater proportion of secondary rocks than either the middle or northern; and hence approaches more nearly to England in a general geognostic point of view. The following secondary formations have been observed:—1. Old red sandstone. 2. Mountain limestone. 3. Coal formation. 4. New red sandstone. 5. Various trap and porphyry rocks.

1. *Old red sandstone.* This formation skirts the transition chains of mountains lying immediately upon the greywacke, &c. It is well exposed in the Pentlands, the upper part of the river district of the river Clyde, in the course of the river Tweed, in various points in Dumfries-shire, &c. In the districts where it occurs, it is frequently quarried and used as a building-stone.

2. *Mountain limestone.* The beds of limestone in the lower part of the coal formation in the neighbourhood of Edinburgh, and the beds of limestone upon which the coal formation rests in other quarters, as in Dumfries-shire, belong to the mountain limestone.

3. *Coal formation.* This important deposit occupies considerable portions of East, Mid, and West Lothian, and extends westward to Glasgow. It forms extensive tracts in Ayrshire; in Dumfries-shire it occurs at Sanquhar, in the lower part of Annandale, and at Cannoby in Eskdale; and in Berwickshire. The coal mines in the Lothians and around Glasgow are the most productive in Scotland. Even one small coalfield, the property of the Marquess of Lothian, in the vicinity of Edinburgh, Mr. Bald has shown, will serve that city at the rate of 350,000 tons yearly, for the long period of 500 years. The annual quantity of coal brought into Glasgow is 561,049 tons: of this enormous quantity, 124,000 tons are exported from the Clyde at the Bromielaw and Bowling Bay, and from Port Eglinton by the Ardrossan canal; so that there remains for the use of families and public works in that city and its suburbs, 437,049 tons. It may also be noticed, as connected with coal, that in Glasgow, during twenty-four hours in the winter months, the gas company make upwards of 500,000 cubic feet of gas from coal; and during the same period in the summer months, about 120,000. The pipes extend to more than 100 miles through streets. The great iron-works at Carron are supplied with the ore from which the iron is obtained, from the coalfields of this and the middle division of Scotland. The ore or stone, which is

an argillaceous carbonate of iron, occurs in beds and embedded masses, and principally in the slate of the coal deposit. The admirable building-stone around Edinburgh and Glasgow is a sandstone which occurs in beds in the coal formation.

4. *New red sandstone.* This formation in the regular succession rests upon the coal formation, in which position it is to be seen in the neighbourhood of Cannoby in Dumfries-shire.

5. *Trap and porphyry rocks.* These Plutonian or ignigenous masses occur in great quantity in many parts: they abound, for instance, all around Edinburgh; forming part of the Calton Hill, Castle Hill, Salisbury Craigs, Arthur Seat, Corstorphine Hill, Blackford and Braid hills, the Pentlands, &c.: the beautiful conical hill named North Berwick Law, the Bass Rock, the Isle of May, Traprain Law, are also of igneous origin, and formed of trap and porphyry rocks. Renfrewshire and Ayrshire also abound in splendid and interesting displays of trap and porphyry; and there, as in all other parts of Scotland where they appear, exhibit numerous relations illustrative of their igneous origin, and the changes they have occasioned in the Neptunian strata in their progress from the interior of the earth. In many parts of the country these Plutonian rocks are used as building-stones, and the greenstone of the trap series affords an admirable material for road-making. The splendid causeways and roads around Edinburgh are of greenstone.

1936. III. *Alluvial rocks.* In various parts of the country there occur deposits of old alluvium, or what is called *diluvium*, and every where the modern alluvium, or that daily forming, meets the eye.

1937. (2.) *Middle division.* This division of Scotland is bounded to the south by the southern division; on the north by the Moray Frith and the great chain of lakes extending from Inverness to Fort William and the Linnhe Loch. It is traversed in a north and south-westerly direction by the Grampian range of mountains, which extends from the Mull of Cantyre to Stonehaven in Kincardineshire, and to the rocky northern coasts of Aberdeenshire and Banffshire. The country in general falls rapidly to the west of this great mountain range, and comparatively gently to the eastward of it: hence the western acclivity is steep and short, the eastern gentle and long. On the eastern acclivity and the low lands connected with it are situated the Sidlay, Ochil, and Campsie hills, forming a pretty continuous range; and Kellie Law, Largo Law, the Lomonds, and the Saline Hills in Fifeshire, forming a less continuous and lower range of hills. Water is abundantly distributed over this district, in the form of rivers, lakes, and springs. The principal rivers flow down the eastern acclivity of the land; such are the Tay, the Esk, Dee, and Don. The river Spey, also, in this division of Scotland, flows down the declivity extending from the northern extremity of the Grampians. Lakes, which are so rare in the southern division, are here abundantly distributed, and exhibit many beautiful and splendid scenes. Of these lakes the most considerable are the following: Loch Lomond, Loch Tay, Loch Ness, and Loch Awe. Although springs are abundant, no one has hitherto enquired in an appropriate manner into their chemical or natural history. The rocks are more varied in this than in the southern division; magnificent displays of primitive, transition, and secondary formations present themselves to our attention.

1938. I. *Primitive and transition rocks.* The Neptunian kinds are granite, gneiss, mica slate, clay slate, talc slate, chlorite slate, quartz rock, greywacke, limestone: the Plutonian rocks are granite, syenite, porphyry, trap, and serpentine. The Neptunian rocks generally range from north-east to south-west; most frequently dip under an angle of about 45° ; and are variously upheaved, broken, and disturbed by the Plutonian rocks. They are principally confined to the Grampian high land and its branches. The most remarkable granite and syenite districts are Cairngorm, Benachie, Aberdeen, Peterhead, Ben Cruachan; and Ben Nevis conjoins along with its slaty Neptunian strata granite, syenite, and porphyry. The granite quarries of Aberdeen and Peterhead, especially the former, have afforded and still continue to yield a large revenue to the proprietors. In some quarters the limestone is raised as marble, as in Glen Tilt; but more frequently it is quarried, and burnt into quicklime. The clay slate quarries of Luss, on the banks of Loch Lomond; those of Balachulish, in Argyleshire; and the slate quarries in the interior of Aberdeenshire, are of considerable extent, and employ many workmen. There are no mines of ore at present worked in the Grampians; but formerly there were lead mines in the neighbourhood of Tyndrum, where the lead glance, or sulphuret of lead, was disposed in veins in quartz rock and mica slate.

1939. II. *Secondary rocks.* These are, old red sandstone, mountain limestone, coal formation, and new red sandstone, and probably the lias formation: these strata are variously intermingled with trap and porphyry rocks.

1. *Old red sandstone.* This rock, in some parts of the country, as in the vicinity of Stonehaven and near Blair-Gowrie, exhibits magnificent cliffs of conglomerate. It forms the principal rock in the great tract of country included between lines drawn from Stonehaven by Blair-Gowrie, Comrie, Callender, Dumbarton, Stirling, Kinross, Dundee, Arbroath, Montrose, and Bervie. It appears again near Inverness, and on the banks of

Loch Ness. In many localities there are extensive quarries, the sandstone being used as a building-stone, and as a pavement-stone. The Kinguddie sandstone and the Arbroath pavement-stone, from old red sandstone localities, are well known.

2. *Coal formation.* The coal formation in the middle division of Scotland has not been met with farther north than Fifeshire. The counties of Fife, Clackmannan, and Stirling, abound in coal; of these counties Fife is that which contains the greatest fields of this valuable mineral.

3. *New red sandstone* occurs apparently in some points on the east coast, and also on the north coast between Cullen and the Cromarty Frith.

4. *Lias formation.* Near to Banff there are beds of clay, which, from the organic remains contained in them, may turn out to belong to this formation.

5. *Plutonian rocks.* These are various traps, as greenstone, amygdaloid, trap tuffa, and basalt; and porphyries, having a basis of claystone or clinkstone. The famous headland the Red Head, on the east coast, exhibits a fine display of Plutonian rocks, connected with the red sandstone. Bervie Head and the vicinity are interesting from their porphyry rocks. The trap rocks of Montrose are famous on account of the agates they afford. Kin-noul Hill, at Perth, is composed of amygdaloid, tuffa, and other rocks of the trap series, and abounds in agates. The Ochil Hills are principally composed of trap and porphyry; and trap rocks abound in the Campsie range. The Fifeshire hills, viz. Kellie Law, Largo Law, the cones of the Lomond, and the Saline Hills, are of trap. These various traps and porphyries have, as is generally the case, broken and changed more or less the Neptunian strata with which they are intermingled.

1940. III. *Alluvial rocks.* These have the same general characters as those met with in the southern division. In a few districts, however, as near to Peterhead, and in the vicinity of Banff, there are numerous *chalk flints*. These, by some, are considered as alluvial, and foreign to Scotland; while others are opinion that they are remains of the chalk formation, formerly distributed in some of the tracts where the flints are found.

1941. (3.) *Northern division.* This division is bounded on the south by the chain of lakes which forms the northern limit of the middle division, and on the north, the east, and the west, by the ocean. It is even more rugged, mountainous, and hilly than the middle division. The high land ranges throughout its whole length, from south-west to north-east. The western acclivity is steep and short; the eastern comparatively gently inclined and long. The principal rivers, none of which, however, are comparable in magnitude with the Tay and the Spey, flow down the eastern acclivity to the sea; others, of less size, flow down the northern acclivity, in the northern part of the country, to the sea; and the least considerable flow down the western acclivity to the western sea. There are a good many lakes, as Loch Shin, and others, mentioned in the geographical account of the country. The springs are numerous, but hitherto observers have passed them by without examination.

The whole of this division, nearly, is composed of primitive and transition rocks, the secondary occurring principally along the east coast and a small extent of the north-west coast.

1942. I. *Primitive and transition rocks.* The Neptunian species are disposed in strata that often range from south-west to north-east, are of gneiss, mica slate, clay slate, quartz rock, talc slate, limestone, and greywacke. The Plutonian rocks are less abundant than in the middle and southern divisions of Scotland; and are granite, syenite, porphyry, and trap. The only mines are those at Strontian, where the ore is lead glance, or sulphuret of lead, in veins traversing gneiss. The mineral in which the *Strontian earth* was first found occurs in these mines, along with other curious minerals, of which the cross-stone is the most interesting.

1943. II. *Secondary Rocks.* The formations of this class are both Neptunian and Plutonian. The Neptunian are old red sandstone, new red sandstone, lias, and oolite; the Plutonian, trap and porphyry.

1. *Old red sandstone.* Much of the county of Caithness, and some tracts on the east coast, and a few points on the west, are composed of this formation.

2. *New red sandstone.* The county of Caithness affords examples of this deposit, which is remarkable on account of the beds of *fossil fishes* it contains.

3. *Lias and oolite.* This formation we noticed many years ago near Brora and other points on the east coast of Sutherland. From the kind of coal associated with the rocks, and their fossil animal remains, we referred them, in a paper read to the Wernerian Society, to a formation newer than the coal and new red sandstone. The precise position of the deposit, and the characters of its organic remains, were first made out by Mr. Murchison, in an excellent paper, read before the Geological Society of London, and published in their Memoirs. The coal mines at Brora are situated in this deposit, and are the most northern mines of this mineral in Britain. The coal is, however, of indifferent quality, and of late years has been less extensively worked than formerly.

1944. *The Plutonian rocks* are not frequent, and consist principally of trap and porphyry.

1945. III. *Alluvial rocks.* These exhibit the same characters as in the middle and southern divisions.

1946. (4.) *Insular division.* This may be subdivided in the following manner:—
1. Forth Islands; 2. Clyde Islands; 3. Hebrides; 4. Orkneys; 5. Shetlands.

1947. (1.) *Forth Islands.* Under this division we include the islands in the Frith of Forth, which are the Bell Rock, Island of May, Bass, Inchkeith, Cramond Island, Inch Columb, and Inch Garvie. The Bell Rock, on which the most perfect and splendid of British light-houses is perched, is of a red sandstone, having the same characters as that on the neighbouring coast at Arbroath. The other islands are principally composed of trap rocks, occasionally associated with clinkstone porphyry, and rocks of the coal formation. Of these, Inchkeith, within a few miles of Edinburgh, is the most interesting in a geognostical point of view; while the Island of May and the Bass Rock present the most striking rocky scenery.

1948. (2.) *Clyde Islands.* These, which are situated in the Frith of Clyde, are the Cumbrays, Bute, Arran, and the Craig of Ailsa.

1949. *The Cumbrays.* Two islands have this name; the one is the so-called Great Cumbray, the other the Lesser Cumbray. They are composed of secondary rocks, partly of Neptunian and partly of Plutonian origin. The Neptunian rocks are chiefly old red sandstone, which is traversed and overlaid by different kinds of trap rocks, of which there are magnificent displays in these islands.

1950. *Bute.* This, which is the most beautiful of the Clyde islands, may be geologically divided into three districts, viz. southern, middle, and northern. The southern is almost entirely composed of rocks of igneous origin, belonging to the trap series; the middle, of old red sandstone; the northern of clay slate, mica slate, quartz rock, and trap. Quarries of clay slate occur in the northern district.

1951. *Arran.* With exception of the Isle of Skye, no island of the British seas presents scenery so imposing and magnificent as Arran. Its geognosy, too, is also very interesting; and as British geology may be said to have arisen in that remarkable island, it will always occupy a prominent place in the history of geology. We gave the first geological account of Arran. The interesting phenomena so abundantly exhibited throughout the island, afterwards engaged the attention of other observers. It would be fruitless, in the space allowed for geology in this work, to attempt to give even a general idea of Arran. We can only say, that it affords highly illustrative examples of Neptunian and Plutonian rocks of the primitive and transition classes, viz. clay slate, mica slate, greywacke, as Neptunian deposits; and granite, as a Plutonian rock. The junctions of the granite, of which there are two formations, with each other and with the Neptunian slates, are most instructive, and annually attract to Arran visitors from all parts of Britain, and even from distant continental countries. Reposing on these rocks is a deposit of the old red sandstone, on which rests the coal formation; and the whole are covered, more or less completely, with new red sandstone. These Neptunian secondary rocks are traversed in all directions by Plutonian rocks of the porphyry and trap series, affording an admirable study to the geologist interested in the natural history of ignigenous formations.

1952. *Alluvial deposits* occur all round the coast, and covering, more or less deeply, the bottom and sides of valleys. Both old and new alluvium are met with in Arran.

1953. *Craig of Ailsa.* This splendid rock which forms so striking an object from the coast of Ayrshire, is 900 feet high, and is composed of secondary syenite, in several cliffs disposed in magnificent columns, and traversed by veins of secondary greenstone, &c.

1954. (3.) *Hebrides or Western Islands.* These lie along the west coast of the mainland of Scotland, and may be described as forming two groups; the one, ranging immediately along the coast, the *Inner Hebrides*; the other, lying beyond, to the westward, the *Outer Hebrides*.

1955. *Inner Hebrides.* The islands of *Gigha, Isla, Jura, Colonsay, Oronsay, Scarba*, the *Slate Islands, Mull, Iona, Staffa, Tiree, Coll, Eigg, Rum, Canna, Skye, Rasay, and Rona*, form the group of the Inner Hebrides. *Gigha, Isla, Jura, Colonsay, Oronsay, Scarba*, and the *Slate Isles* are principally composed of Neptunian primitive and transition strata, having frequently a north-east and south-west direction; and variously disposed, from the slightly inclined to the vertical position. The rocks are mica slate, quartz rock, talc slate, chlorite slate, hornblende slate, clay slate, limestone, and greywacke. These are traversed by, and intermingled with, Plutonian rocks of the trap and porphyry series. The clay slate is extensively quarried in the isle of Eisdale, one of the Slate Islands. In *Isla* there is a great deposit of limestone, in which formerly lead mines were worked. *Iona, Tiree*, and *Coll* are principally composed of gneiss, mica slate, quartz rock, hornblende rock, with occasional intermixtures of granite and syenite, and all traversed, more or less frequently, by veins of trap rock. *Mull*, one of the largest of the Hebrides, with the exception of the Ross of Mull, and one or two other points, which are composed of granite, gneiss, and mica slate, is composed of secondary trap and porphyry rocks, with occasional intermixtures of lias limestones, and lias coals. The usual alluvial deposits appear in different parts of the island. *Staffa*, which is composed of basalt, amygdaloid, and trap tuffa, has been long celebrated on account of its splendid columnar basaltic cave, the Fingal's Cave of travellers.

Eigg is principally composed of trap rocks, occasionally intermingled with lias limestones. The *Scure Egg* is a remarkable columnar ridge of pitchstone porphyry (which we first described many years ago), presenting the most splendid display of the natural columnar structure to be met with any where in the British islands. *Canna* is entirely composed of secondary trap rocks; and *Rum*, a wild, rugged, and hilly island, besides red sandstone, which forms a prominent constituent part, also contains many varieties of trap, some of which are remarkable from their containing agates, bloodstone, opal, &c. *Skye*, the largest of the Inner Hebrides, exhibits great variety of scenery and of geological arrangement. The scenery of *Coruisk* is the most savage any where to be seen in Britain. The *southern part* of the island is composed of primitive and transition rocks, principally of the Neptunian series; namely, mica slate, clay slate, chlorite slate, hornblende rock, quartz rock, greywacke, and limestone. The *middle part or division* affords magnificent displays of Plutonian rocks, as syenite, porphyry, and trap, which are frequently observed intermixed with lias limestone, which in many places is seen converted into marble through the agency of those ignigenous rocks: the *northern division* of the island is principally composed of various trap rocks, often abounding in zeolite and other curious minerals, and intermingled with lias limestone and coal. The alluvium here exhibits its usual characters. *Rasay*. The southern and middle parts of this island are of secondary formation, principally of old red sandstone and lias sandstone; the northern extremity is of primitive rocks, principally gneiss. *Rona*. This island, which appears formerly to have been a part of *Rasay*, is entirely of primitive formation, the prevailing rock being gneiss, with subordinate mica slate, quartz rock, hornblende rock, &c., traversed by splendid veins of granite.

1956. *Outer Hebrides*. This group, which lies in a north-east and south-west direction, consists of the following islands; viz. *Lewis*, *Harris*, *North Uist*, *South Uist*, and *Barra*. The whole range of islands is nearly of primitive formation, and the predominating rocks, which are gneiss and mica slate, range generally from north-east to south-west. The following rocks, which are generally subordinate to those just mentioned, viz. quartz rock, clay slate, chlorite slate, hornblende rock of various kinds, limestone (?), serpentine, with masses and veins of granite, syenite, and porphyry, present many interesting phenomena.

1957. (4.) *Orkney Islands*. This group of islands is distinguished from all the others that lie around the coasts of Scotland, by the uniformity of its structure and composition. With the exception of a small extent of transition rocks near *Stromness* in the island of *Pomona*, the largest of the *Orkneys*, that island and all the others are composed of the old red sandstone, with some rare appearances of secondary trap.

1958. *Fair Isle*. Judging from the specimens sent to us, never having landed on that secluded spot, it appears to be entirely composed of old red sandstone.

1959. (5.) *Shetland Islands*. This very interesting group of islands exhibits great variety in its geognostical structure and composition, and affords an admirable field to the student of geology for the study of the older rocks of which the crust of the earth is composed. The following are the principal islands of the group: *Mainland*, the largest island, *Unst*, *Fetlar*, *Yell*, *Whalsey*, *Bressay*, *Barra*, *Mousa*, *Papa Stour*, and *Foula*.

1960. *Mainland*. With the exception of a band of old red sandstone extending from the line of *Sumburgh Head* to *Rovey Head*, on the east coast, the whole of this island is formed of primitive rocks. These are partly Neptunian, partly Plutonian. The Neptunian strata are gneiss, with subordinate mica slate, clay slate, quartz rock, limestone, and hornblende rocks; the Plutonian rocks, which frequently alter and upraise the Neptunian strata, are granite, syenite, porphyry, greenstone, and epidotic syenite.

1961. *Yell*. This island, next in size to the *Mainland*, is almost entirely composed of gneiss, variously intersected by veins of granite.

1962. *Unst*. This interesting island, the next in magnitude to *Yell*, is composed of gneiss, mica slate, talc slate, chlorite slate, and limestone, which are variously intermixed with serpentine and diallage rocks. *Hermaness*, the most northern point of the British dominions in Europe, is composed of gneiss; while the *Land's End* of *Cornwall*, the most south-westerly cape of Britain, is formed of granite. *Unst* and the neighbouring island of *Fetlar* abound in chromate of iron. This valuable ore we met with in *Unst* many years ago; afterwards it was found in great quantities by Dr. *Hibbert*, and has afforded a large annual income to some of the proprietors. Hydrate of magnesia, grenatite, precious garnet, and other beautiful minerals, occur in this island.

1963. *Fetlar*. This island is smaller than *Unst*. It is composed of serpentine as the predominating rock, with diallage rock, gneiss, mica slate, chlorite slate, and quartz rock.

1964. *Whalsey*, which is still less extensive than *Fetlar*, is composed of gneiss.

1965. *Bressay*, *Noss*, and *Mousa*. *Bressay*, which with the mainland forms the famous bay of *Lerwick*, as also the isle of *Noss*, are composed of old red sandstone; and the island of *Mousa*, some miles to the south of *Lerwick*, is composed of the same sandstone formation.

1966. *Barra, House, and Papa Stour.* The two first-mentioned islands are composed of gneiss and mica slate, with subordinate limestone; while Papa Stour is a mass of porphyry. In the porphyry of this island we, many years ago, found, in drusy cavities of the rock, crystals of a mineral very abundant in England, but very rare in Scotland, viz. fluor spar.

1967. *Foula.* This isle, the *Ultima Thule* of some authors, is the most western and most remote of the Shetland islands. Its coast scenery, on the west side, facing the storms of the Atlantic Ocean, is most magnificent. The predominating rock is old red sandstone; at one point there is a limited display of primitive rocks of granite, gneiss, mica slate, and clay slate.

SECT. III. *Historical Survey.*

1968. *To the Greek and Roman writers, Scotland* was less known than, perhaps, any other part of Europe, if we except Scandinavia. It was not, indeed, recognised as a distinct country under that or any other name. Albion, or Britain, was viewed as one region, parcelled out among a multitude of different tribes. Agricola first penetrated into that part of Britain which we now call Scotland. He easily over-ran the low country, but encountered a most obstinate resistance when he approached the Caledonians, who appear then to have held all the northern districts. An obstinate battle, the precise place of which has never been ascertained, was fought at the foot of the Grampians. All the rude valour of Caledonia could not match the skill of Agricola and the discipline of the Roman legions. The whole open country was abandoned to the invaders, whose progress, however, was stayed by what they termed the Caledonian forest, under which they seem to have vaguely comprehended the vast pine woods of Glenmore and the steep barrier of the Grampians. Their military occupation, however, is attested by the formation of numerous camps, of which that at Ardoch (*fig. 186.*), ten miles north of Stirling, is the most extensive and complete.

186

CAMP AT ARDOCH.

From these mountain bulwarks, however, our ancestors rushed down, and made their name terrible to the conquerors of the world. The Romans endeavoured to resist their incursions by rearing, at different periods, two walls, one between the Forth and Clyde, and the other south of the low country of Scotland, between the Solway and the Tyne. The northern tribes, however, continued their inroads, now chiefly under the name of Picts, who seem clearly to have been the same people with the Caledonians. In the fifth century, Britain was abandoned by the Romans, and over-run by the Saxons, who occupied the eastern part of the south of Scotland as far as the Forth.

1969. *The western part was formed into the kingdom of Strathclyde.* It flourished for about 300 years, and was rendered illustrious by the name and

exploits of Arthur and his knights, whose power, from 508 to 542, is represented by tradition as having been predominant over the south of Scotland and the north of England. The capital and bulwark of this kingdom was Alclud, called afterwards Dun Briton and Dumbarton, seated on an insulated precipitous rock at the mouth of the Clyde. The Strathclyde Britons, closely pressed by their Saxon neighbours, endeavoured to defend themselves by a lengthened *fosse*, of which the traces have been supposed to remain in the Catrail or Picts'-work Ditch, drawn across the counties of Selkirk and Roxburgh. Such feeble defences could not support a sinking monarchy; in 757, Alclud was taken by the Saxons, and the kingdom subverted.

1970. *The Scots*, before this time, had come from Ireland, their original seat, which, in the fourth century, was often called Scotland. Even before the departure of the Romans, the Scots, joined with the Picts, are mentioned as the ravagers of defenceless Britain. They appear at one time to have been driven back into Ireland; but in 503 they again landed in Cantyre, and during the next four centuries spread gradually over the kingdom. At length, under the victorious reign of Kenneth, which commenced in 836, they wrested the sceptre from Wred the Pictish king, and established supreme sway over the whole of that country, which, from them, was ever afterwards called Scotland.

1971. *The Scoto-Saxon era*, as Mr. Chalmers calls it, is memorable rather for an insensible

change, than for any sudden revolution. After the subversion of the kingdom of Strathclyd, by the Saxons, that people had colonised and filled the whole south; and the Scottish kings, though of Celtic origin, having established themselves in this more fertile part of their territories, soon began to imbibe the spirit of its occupants. From this or other causes the whole lowlands of Scotland is in language and manners Teutonic, and the Gael or Celts were again confined within their mountain boundary.

1972. *An era of disputed succession* arose out of the contending claims of Bruce and Baliol, after the death of Margaret of Norway. Edward I., availing himself of this dissension, succeeded in introducing himself under the character of an arbiter, and having established Baliol on the throne by an armed interference, sought to rule Scotland as a vassal kingdom. The result was a struggle, calamitous to Scotland, but which, however, placed in a conspicuous light the energy and heroism of the nation, and brought forward the names of Wallace and Bruce, ever afterwards the foremost in her annals. The result was glorious; the concentrated force of the English was finally defeated in a pitched battle at Bannockburn; they were compelled to renounce their ambitious pretensions, and allow the kingdom to be governed by its native princes.

1973. *Under the turbulent and unfortunate sway of the Stuarts*, Scotland continued for several centuries without any prominent revolution, though with a continued tendency to internal commotion. This dynasty, from their connection with the French and English courts, had acquired the idea of more polished manners, and habits of greater subordination as due from the nobles. Such views were ill suited to the power and temper of a Douglas, and many other powerful chieftains, through whose resistance the attempts of the monarchs were followed with disaster, and often with violent death. The introduction of the reformed religion especially, in open opposition to the court, which granted only a reluctant and precarious toleration, was unfavourable to the crown, and fatal to a princess whose beauty and misfortunes have rendered her an object of enthusiasm to the gay and chivalric part of the Scottish nation.

1974. *The union of the crowns*, by the accession of James VI. in 1603, to the English throne, produced a great change, in itself flattering to Scotland, whose race of princes now held sway over all the three kingdoms. As, however, they immediately transferred their residence to the wealthy capital of England, the actual result was to reduce Scotland somewhat to the condition of a province; but these disadvantages were finally incalculably overbalanced by subsequent benefits.

1975. *The struggle between presbytery and prelacy*, which formed the first instance of this interference, gave rise to a conflict which is still deeply remembered, and powerfully influences the temper and character of the Scots. Presbytery, their favourite form of church government, was supported by the nation with an enthusiastic determination which strongly influenced the general destinies of the empire. The efforts of the presbyterians, acting under the bond of their League and Covenant, first enabled the English parliament to rear its head, and had a great effect in turning the scale of contest against the crown. The Scots revolted, however, at the violent excesses of the independents, and endeavoured to rear again, on a covenanted basis, the fallen crown of the Stuarts. These brave but unsuccessful efforts were very ill requited by Charles II., on his restoration, by an embittered persecution against all the adherents of presbytery. They maintained its cause with unequal means, till the Revolution finally fixed that system as the established religion of Scotland.

1976. *The union of the kingdoms*, in 1707, placed Scotland in that political position which she has ever since maintained; and, by allaying internal contest, and opening a free trade with the sister kingdom, this union has produced results highly beneficial. Some clouds still lowered over the political horizon of Scotland. The devoted attachment of her mountain tribes to the exiled Stuarts repeatedly impelled them to make brave though misguided attempts to replace that house on the throne; attempts which, at one critical moment, spread alarm into the heart of England. In other respects, the majority of the nation have been distinguished for their loyalty, and have even been accused by their opponents of an excess of subserviency to the views of the crown. Some temporary effervescence at the commencement of the French revolution, and during the period of manufacturing distress, can scarcely amount to an exception to this general remark.

SECT. IV. *Political Constitution.*

1977. *The political system of Scotland* being now almost completely incorporated with that of England, little is to be added to the statements given under the head of the sister kingdom. A few peculiarities, however, may be deserving of notice.

1978. *The representation allowed to Scotland* at the union was somewhat scanty. It consisted, for the House of Commons, of forty-five members, fifteen from the boroughs, and thirty from the counties. The boroughs, however, amounting by the ancient constitution to sixty-six, were divided into classes of four or five, one member being returned by the majority of each class. Edinburgh alone returned one member. The friends of liberty were the less disposed to murmur at so small an allotment, as the constitution of these boroughs was far

from popular. The members were elected, not by the inhabitants as burgesses, but by the magistrates, who themselves were appointed chiefly by their predecessors in office; thus constituting close boroughs, in which a party having once obtained a majority might keep it *in perpetuum*, with little regard to the judgment of their fellow-citizens. In county elections, also, there were some anomalies. The right of voting was attached to the possession of lands held immediately of the crown, and of the valued rent of 400*l.* Scots. But the feudal superiority which entitles to vote was separable from the actual possession of the property. The original proprietor, who, perhaps, had a number of these *votes* on his estate, might either sell or distribute them among his friends, so as to multiply his own elective influence. The freeholders of Scotland amounted to not quite 3000, of whom a certain number, for the reason stated, had no actual property in land. The peers of Scotland are represented by sixteen of their number, elected at the commencement of each parliament. There are, besides, upwards of twenty who are British peers, and sit in their personal right.

1979. By the Reform Bill of 1832, the power of returning members to the House of Commons is vested in the following cities and burghs: —

	Members.
Edinburgh	2
Glasgow	2
Aberdeen	1
Paisley	1
Dundee	1
Greenock	1
Perth	1
Leith, Portobello, Musselburgh	1
Kirkwall, Wick, Dornoch, Dingwall, Tain, Cromarty	1
Fortrose, Inverness, Nairn, Forres	1
Elgin, Cullen, Banff, Inverary, Kintore, Peterhead	1
Inverbervie, Montrose, Arbroath, Brechin, Forfar	1
Cupar, St. Andrew's, Anstruther Easter and Wester, Crail, Kilrenny, Pittenween	1
Dysart, Kirkaldy, Kinghorn, Burntisland	1
Inverkeithing, Dumfermline, Kinross, Queensferry, Culross, Stirling	1
Renfrew, Rutherglen, Dumbarton, Kilmarnock, Port Glasgow	1
Haddington, Dunbar, North Berwick, Lauder, Jedburgh	1
Linlithgow, Lanark, Falkirk, Airdrie, Hamilton	1
Ayr, Irvine, Campbellton, Inverary, Oban	1
Dumfries, Sanquhar, Annan, Lochmaben, Kirkcudbright	1
Wigton, New Galloway, Stranraer, Whithorn	1
	23

These members are returned, not, as formerly, by the town councils of the respective burghs, but by every inhabitant paying rent to the value of 10*l.* and upwards. The counties continue each to elect a member, except that only one in conjunction is returned by Elgin and Nairn, one by Ross and Cromarty; and one by Clackmannan and Kinross. The power of voting, too, is attached not to feudal superiorities, that were often fictitious, but to the possession of actual property yielding 10*l.* of yearly rent.

1980. The judicial administration of Scotland has always continued distinct from that of the sister kingdom. The supreme court, or Court of Session, consisted, until lately, of fifteen members, sitting together, and deciding in all civil causes, while six of these constituted a Justiciary Court for the trial of criminal cases. The trial by jury was employed only in the Justiciary Court, and in revenue questions, which are tried before the Court of Exchequer. There lies an appeal, in every civil case, to the House of Lords, whose judgment is supposed to be almost always guided by the opinion of the Lord Chancellor. Whether from some defect in the Scottish system, or from an opinion that causes would be tried in England on different legal principles, the number of appeals increased to an enormous amount, occasioning a most inconvenient expense and delay. For the remedy of these evils, as well as with a view to economy, considerable changes have, within the last few years, been introduced, chiefly tending to assimilate the procedure to that of the English courts.

1981. The supreme court was divided into two chambers, one of seven and the other of eight members; and these have been recently reduced to six and seven; making the whole number thirteen. Trial by jury, in civil cases, was introduced, and conducted before a separate court, called the Jury Court, presided by a lord chief commissioner. This, too, has been recently abolished; and these trials are now carried on, like others, under the direction of the Court of Session. The Court of Exchequer, which consisted once of five barons, was

first reduced to three, and is now so far abolished, that, on the death or retirement of the present members, it is no longer to have any judges of its own, but one lord of session is to devote one day of the week to the trial of causes belonging to its jurisdiction. The Consistory and the Admiralty Courts have also been abolished, and their jurisdiction transferred to the Court of Session.

1982. *The revenue of Scotland* has been hitherto collected separately from that of England, and by separate boards for each branch ; but, under recent regulations, the whole has been placed under the direction of boards resident in London, and the systems have been in a great measure incorporated together. In the year ending 5th January, 1831 —

	£
The Scottish excise was	2,395,490
Customs	1,357,000
Stamps	526,000
Assessed taxes	292,000
Post-office	201,000
	4,771,490

1983. *The branches of excise duty* were —

	£		£
Auctions	18,400	Malt	466,000
Beer	76,100	Paper	94,000
Candles	9,500	Printed goods	374,000
Glass	123,500	Soap	140,000
Hides	39,000	Spirits, British	1,274,000
Licences	112,000	Starch	10,000

1984. *The principal branches of stamp duty* were —

Newspapers	42,000	Legacies	58,000
Advertisements	28,600	Fire insurances	50,000

1985. *Under the head of taxes* came chiefly —

Windows	66,000	Horses	21,800
Houses	82,000	Dogs	14,000
Servants	25,000	Game duties	12,000
Carriages	25,000	Armorial bearings	2,900

1986. *The chief branches of the customs* will be given under the head of trade.

1987. *The army and navy in Scotland* are entirely under the general system of the United Kingdom. There are, however, a number of regiments bearing Scottish names, as having been originally raised, and usually, though not always, recruited, in Scotland, and officered by Scotsmen. The Highland regiments are even allowed to retain some remnant of their national dress, and fought with signal glory in the British ranks during the late war. Scotland, being little exposed to external danger, has usually stationed within itself only a small proportion of each force, particularly the naval.

SECT. V. *Productive Industry.*

1988. *Scotland has always ranked as a poor country*; and, indeed, our survey of its outline and surface must have shown how very difficult it must be for her to avoid coming under this character. For a long time, unfortunately, natural obstacles were enhanced by moral impediments. The Scots showed an extreme aptitude to embark in all schemes of turbulence and enterprise ; but indolence, and dislike of plain hard work, might be recognised as a national characteristic. Since the age arrived, however, when industry came into honour, and when improved processes were studiously applied to all the useful arts, the Scots have entered with peculiar spirit and intelligence into this new career ; and in its prosecution have been more successful, in some respects, than their southern neighbours.

1989. *The agriculture of Scotland* has to contend with obstacles which must be manifest, when we look at its rugged aspect, and its vast hills and morasses. Forty years ago, moreover, the progress of Scotland in this primary art was very generally behind that of the rest of the empire. The farms were mostly small, and tilled in a slovenly manner, with half-starved horses, four of which were yoked in the plough ; while parts of each farm were alternately cultivated or left waste, upon the rude plan of infield and outfield. As soon, however, as the great system of agricultural improvement was adopted throughout the kingdom, the Scottish farmers not only shared in it, but carried it farther than those of England, who were attached in an almost superstitious degree to that routine which had enriched themselves and their forefathers. The farmers of the Lothians, of the Carse of Gowrie, and even of

the district on the Moray Frith, made a rapid and complete reform in the whole train of agricultural operations. They brought extensive tracts of common and waste under cultivation, reduced the number of cattle and improved the breed, cultivated the artificial grasses, dismissed superfluous hands, and adopted the use of machinery, of which the most important, the threshing machine, was entirely of Scottish invention. The consequence was, that considerable fortunes were made by successful farmers, and that rents were in almost every instance trebled, and in some cases raised to eight or ten times their former amount. In the mountainous districts, also, a new system was introduced, which proved more profitable to the landlord, and perhaps to the country, but was attended with some painful circumstances. The numerous little farms hitherto held by tenants or vassals, were thrown into extensive sheep-walks. Considerable depopulation, in the agricultural districts, was the consequence; a great proportion of this brave and warm-hearted race were forced to quit their native glens, to which they were fondly attached, and to seek support, either in the great manufacturing towns, or in settlements formed on the other side of the Atlantic.

1990. *The cultivated lands of Scotland*, and the amount of its produce, after all these improvements, are still limited. Of the 18,944,000 acres, its computed extent of land, only 5,045,000 are reported as under regular cultivation. The Board of Agriculture, in their report, do not calculate more than 1,800,000 acres actually under grain. Of these only 140,000 produce wheat, though this is considered the most profitable crop, and is raised of good quality, where the soil and climate admit; but it is chiefly on the fine carse lands on the shores of the eastern friths. It may yield, perhaps, a million of bolls, which, as wheaten bread is not much used by the body of the people, may suffice for internal consumption. Oats, a hardy plant, and adapted to cold climates, is the staple produce of Scotland, and the food of its rural population: it covers 1,260,000 acres. Barley occupies 280,000 acres, being raised chiefly for the purpose of distillation; but in the higher districts it is not barley proper, but that ruder species called *bear* or *big*. Flax is raised in some of the upper districts, but not nearly sufficient for the national manufacture. The chief exportable produce consists in cattle and sheep, which are sent in great numbers to the English markets, though large imports from Ireland have lessened the demand for Scottish cattle in the north-western counties. The sheep are not equal to the fine English breeds, and the fleeces of Scotland are not peculiarly valuable; but the mutton produced on the steep sides of the Grampians and Cheviots is of exquisite flavour.

1991. *The manufacturing industry of Scotland* has also, within the last half century, advanced with prodigious rapidity, being quite equal, compared with the extent and population of the country, to that of England. The Scots, indeed, never showed any want of diligence in fabricating their national stuffs; but the means used were chiefly the old and simple implements, the spindle, distaff, and single loom of the village weaver. Now, however, the use of skilfully constructed and extensive machinery, and the division of labour produced by assembling the working classes in large factories, have immensely increased the productive powers of industry.

1992. *Woollen*, in the form of cloth, the grand original staple of England, has never obtained more than a very partial footing in Scotland. The knitting of woollen stockings, however, for domestic use, has generally supplied the nation with this useful article, which in Aberdeen and Shetland became an object of trade. But now that the English looms produce that article so cheap, this branch of labour scarcely finds its price; with the exception, perhaps, of the Shetland hose, whose fine and peculiar fabric is not yet rivalled.

1993. *Linen, with other products of flax*, is the old original staple of Scotland. It was throughout the country a household manufacture, and for household use. Flax, in almost every family, was diligently spun into yarn, which was then sent out to be woven and bleached. In Forfarshire, and other northern lowland counties, the coarser goods, sailcloth, sackcloth, canvass, &c., have always been produced in great quantities; while in Glasgow and Paisley, the material was wrought into the finer ornamented forms of lawns, cambrics, &c. This last manufacture, however, has now entirely given place to that of cotton, which is almost exclusively carried on in the west of Scotland. The coarser kinds of linen still form the staple of the eastern counties, though Dunfermline excels in fine sheeting and diaper. The average value is not supposed to exceed one shilling per yard. Since 1727, a board has been established at Edinburgh for the encouragement of this branch of industry, and formerly all the cloth made for sale was required to be stamped by their authority; but now their functions extend to little more than the granting of premiums. The linen made in Scotland was estimated, in 1730, at 3,755,000 yards, value 131,000*l.*; and in 1810, at 26,457,000 yards, value 1,265,000*l.* The increase in the manufacture has since been so great, that in 1831, Dundee alone exported more than 57,000,000 yards! By far the greater proportion of the raw material is imported, very little hemp or flax being grown either in Scotland or England; almost all the former, and more than half the latter, is brought from Russia, the rest of the flax from Holland, Flanders, and Germany.

1994. *The cotton manufacture*, though of comparatively recent introduction, has, in Scot-

land, no less than in England, risen to be the first in point of magnitude. Glasgow and Paisley produce fabrics highly ornamented, and carried to an extreme degree of fineness. The muslin of Paisley is one of the most delicate fabrics existing. The printing of cottons, particularly shawls, is also carried on to a greater proportional extent in Scotland than in England. According to the best authorities, the total quantity of cotton wool spun in Great Britain, in 1832, amounted to 277,000,000 lbs. Deducting from this sum 30,000,000 lbs. for loss in spinning, there remains 247,000,000 lbs., of which the proportion spun in England is estimated at 222,500,000 lbs., and that spun in Scotland at 24,500,000 lbs. Hence, valuing the whole manufacture at 34,000,000*l.* the proportion belonging to Scotland will be about *one ninth* part, or 3,777,000*l.* These statements have been derived from the article *COTTON*, in the 2d edition of *M'Culloch's Commercial Dictionary*, and may be regarded as approaching as nearly to accuracy as the subject will admit.

1995. *Distillation of spirits from grain* has been long a characteristic branch of Scottish industry; and in the highland districts, the quality of the article has been carried to very great perfection. It has been much cramped by injudicious fiscal restrictions, compelling the manufacture to be carried on in the mode best suited for raising a revenue. Whiskey was allowed to be made only in large stills. Highland whiskey could not be carried beyond the boundary, neither could that of Scotland, except under most inconvenient limitations, be exported to England. A most extensive and ruinous contraband trade was the inevitable consequence. Government of late have almost entirely abolished these absurd restrictions, and have even reduced the duty, which was once 8*s.*, to 3*s.* 4*d.* a gallon. These measures have had such an effect in increasing the production, and checking contraband trade, that the revenue has scarcely suffered at all, even by the great reduction of duty. In the first seven years of the present century, the quantity paying duty averaged 2,000,000 gallons; it then rose to 3,000,000, and gradually approached to 4,000,000; but in 1824, upon the reduction of the duty, it suddenly increased to above 5,000,000, to which point it has since been fully kept up. In 1829, the produce was 5,777,000 gallons; and in 1830 it rose to 6,070,000.

1996. *Scotland has various other ordinary manufactures*, and generally supplies itself with all the common necessities of life. In regard to *malt liquors*, it cannot indeed rival London in *porter*; but the ale of Edinburgh and of some Scottish towns enjoys reputation even out of Scotland. In 1829, there were brewed in Scotland 110,000 gallons of strong beer, and 229,000 of table beer. *Glass* is made to the extent of nearly double the consumption of the country; the surplus being exported, chiefly to Ireland. *Salt*, which does not exist in a mineral form, is largely extracted from sea water by boiling; and though not equal in quality to English rock salt, nor fit for use in the fisheries, its cheapness recommends it for common culinary purposes. Candles, soap, starch, leather, paper, are produced in every large town and its neighbourhood in quantity sufficient for the supply of the inhabitants. In 1829, the produce was 5,731,000 lbs. tallow candles; 12,721,000 lbs. hard soap, and 2,332,000 lbs. soft soap; 812,000 lbs. starch; 6,002,000 lbs. hides; 7,162,000 lbs. paper. Bricks are also made; but from the abundance of fine freestone and granite, they are little employed, unless for party walls. In 1829, there were made 25,741,000 common, and 396,000 large bricks; also 2,854,000 pantiles.

1997. *The mineral wealth of Scotland* is chiefly of an humble and useful description. Its mountains are not metalliferous. Throughout the whole of the grand highland range there are scarcely any veins worth working. The less elevated southern ranges have a better reputation. On the high border of the counties of Lanark and Dumfries is a large depository of lead mixed with silver, which, together with some smaller mines in the Hebrides, is supposed to yield 136,000*l.* in the former metal, and 10,000*l.* in the latter. Ironstone occurs extensively in the upper coal districts. In 1825, the annual production of pig iron in Scotland was as follows:—

				Blast Furnaces.		Tons.
At Clyde works,	-	-	Lanarkshire	-	3	- 4500
At Calder, ditto	-	-	ditto	-	4	- 4000
At Shotts, ditto	-	-	ditto	-	2	- 2000
At Wilsontown, ditto	-	-	ditto	-	2	- 3500
At Omon, ditto	-	-	ditto	-	2	- 1500
At Muirkirk, ditto	-	-	Ayrshire	-	3	- 5000
At Devon, ditto	-	-	Clackmannanshire	-	3	- 3700
At Carron, ditto	-	-	Stirlingshire	-	5	- 5000
					24	- 29,200

Of which in blast - - 17;

which is not, however, sufficient to supply the founderies at Carron and elsewhere. Those at Carron are considerable, the casting being chiefly of ordnance, grates, and culinary vessels; but Scotland does not pretend to rival her neighbour in the fine and varied forms of hardware. Coal, lime, and stone compose the solid mineral wealth of Scotland. The great coalfield extends in a diagonal line of 100 miles along the friths of Clyde and Forth; beginning south of the former, and ending north of the latter. It is immensely rich in coal of various kinds, and generally of pretty good quality, though not reckoned equal to the very best English. From the west, a large quantity is exported to Ireland. Lime is furnished abundantly, both for building and manure; the annual value being estimated at 35,000*l.* Freestone,

chiefly on both sides of the Forth; granite, in Aberdeenshire; slate, in the Hebrides and Argyleshire, afford copious and excellent materials for building.

1998. *The fisheries* form a considerable branch of industry in Scotland, and one for which her situation is peculiarly favourable. The great extent of the coasts, the deep sounds and bays by which they are every where indented, afford large scope for its exercise. Scotland is not celebrated for any rare or delicate kinds of fish; but the herring, cod, and haddock abound on various parts of its shores. The Dutch long monopolised the great northern herring bank; and, by a superior mode of cure, obtained a preference in all markets. The British government, however, has for some time made great exertions for the promotion of the Scottish fisheries; and there has been a wonderful increase in the quantity caught, and a corresponding improvement in the processes of cure. The former, which in 1815 was only 160,000 barrels, had risen in 1830 to 329,000; of which 336,000 were cured, gutted, and packed within 24 hours after being caught; this despatch being considered essential to their good quality. There were exported to Ireland 115,000 barrels; 40,000 to the continent of Europe; and 82,000 to the West Indies and other places out of Europe. In the same year, 63,500 cwt. of cod were cured in a dried state, and 5400 cwt. in pickle; of the former, 23,000 were exported. Haddocks to the supposed value of 20,000*l.* or 30,000*l.* are taken on the north coast, and slightly cured for the use of the neighbourhood. Salmon taken in the Tweed, the Tay, the Dee, and all the considerable rivers, and kept fresh by being packed in ice, chiefly supplies the London market. The whale fishery in Greenland and Davis's Straits has for some time been prosecuted by Scotland with great and increased activity; while that carried on by England has declined. In the nine years ending in 1818, she sent at an average only 40 ships: in 1830, she sent 47; the produce of which was 5613 tuns of oil. The sea fishing, for the supply of the capital and other towns in the south, is not very active. Kelp, a product obtained by the incineration of common sea-weed, and employed in the manufacture of soap and glass, was in extensive demand during the late war. Its produce in Scotland was estimated at 16,000 tons, worth about 20*l.* a ton. But the repeal of the duty on salt, and the reduction of the duty on barilla, have ruined this branch of industry. The price of kelp has fallen to 4*l.* per ton, and the manufacture has been nearly put an end to.

1999. *Some idea may be formed of the principal foreign articles used in Scotland* by the amount of custom duties levied on each in the year to the 1st January, 1830; though much is imported direct from England:—

Sugar	-	-	-	£ 501,000	Cotton wool	-	-	-	£ 11,000
Tobacco	-	-	-	273,000	Seeds	-	-	-	11,000

2001. *Commerce*, till the union of the crowns, and even of the kingdoms, could scarcely be considered as existing in Scotland; but it has since been cultivated with an ardour and enterprise almost excessive. One branch of commercial intercourse from which the

country of course derives the greatest advantage, is that with her opulent sister kingdom. In England she finds a market for cattle, her chief agricultural surplus; for her wool, such as it is; for her sail-cloth and other coarse fabrics from flax and hemp; for part of her fine calicoes and muslins; for the salmon of her rivers, and some part of the fish cured on her shores. In return, she receives almost all the woollen cloth, and a great part of the silk consumed by her; hardware and cutlery of every kind; tea and other East India goods; and through this channel a part of all the foreign luxuries which she requires. The trade with Ireland is chiefly supported by the exchange of coal and iron for oats and cattle. That with the Baltic, particularly Russia, is very active; the eastern part of the kingdom deriving thence the hemp and flax, which form the material of her staple manufacture; also timber, iron, and the other bulky and useful staples of that trade. Having few articles of her own with which this market is not already stocked, the payment is made chiefly in bullion and colonial produce. The flourishing trade carried on from the west coast with America and the West Indies, is supported by the export of cottons, linen, wearing apparel, and other commodities; and by the import of cotton, sugar, rum, and the various luxuries of those fertile regions. The Mediterranean trade is not neglected; and since the opening of that to India, Greenock has adventured into it with considerable success.

2002. *The communication by roads and canals*, which half a century ago was remarkably defective in Scotland, is now wonderfully improved. The roads, then almost impassable, are now, through all the Lowlands, conducted upon the turnpike system, and have become very little inferior to those of England.

2003. *Artificial navigation meets with peculiar obstructions*, from the ruggedness of the surface; and hence canals have never become very numerous. At an early period, however, a public work of this class, on a most extensive scale, was undertaken by some citizens of Glasgow and Edinburgh. In 1768, they obtained an act of parliament to form the "Great Canal," by which vessels of considerable size might pass from the Frith of Forth to that of Clyde, and thus unite the German and Atlantic oceans. Like some other Scottish undertakings, it was on a scale rather beyond the means of the spirited speculators; repeated pauses, occasioned by want of funds, interrupted its progress; and the returns were long very scanty. In 1778, government, duly appreciating the value of the undertaking, came forward with a loan of 50,000*l.*, by the aid of which, in 1790, the communication was completed from sea to sea. From this time its revenue advanced rapidly, and now amounts to about 60,000*l.* a year; being 25 per cent. on the original capital. Branches to Glasgow and to the fine coalfield at Monkland were advantageously opened. A grand subsidiary has lately been formed, in the Union Canal, commenced in 1822, and rapidly completed, though at an expense of nearly 400,000*l.* It connects the Great Canal, near its eastern point, with Edinburgh, by a line of thirty miles through a country very rich in coal and lime. A tunnel of about three quarters of a mile, and three large aqueduct bridges, have been required; but, by a somewhat winding route, all lockage has been avoided. The produce, unfortunately, has not fulfilled the hopes of its proprietors, who have not yet received any dividend upon the capital invested in this undertaking.

2004. *Southern Scotland* was thus enabled to supply her own wants; but the *northern communications* leading through a poor country, intersected in almost every direction by mountains, ravines, and torrents, could not be carried to perfection by mere local resources. After the rebellion of 1745, government constructed excellent roads into the heart of the Highlands as far as Inverness; and these, though formed with a military view, served other valuable purposes. In 1803, with exclusive regard to the commercial interests of the Highlands, a body of commissioners was appointed by government, and a considerable sum placed at their disposal, to be employed in improving the roads of the north of Scotland. They proceeded upon the wise principle, that half the expense must in every case be defrayed by the county proprietors. The latter concurred, with great ardour, in the views of administration; and in eighteen years good roads were formed into the remotest tracts of Inverness, Skye, Ross, and even to the farthest point of Caithness. The total sum expended in 1821 was 454,000*l.*, and the length of road thus made was upward of 900 miles; for the completion of which it has been necessary to construct 1117 bridges; most of them, indeed, of only one arch.

2005. *The Caledonian Canal* is a more magnificent but hitherto less useful undertaking. The chain of lakes which crosses Scotland diagonally through the counties of Inverness and Argyle, suggested the idea of a water communication, by which large merchant vessels, and even ships of war, from the east coast, might pass into the Atlantic, without encountering the perils of the Pentland Frith and Cape Wrath. This great work was accordingly begun in 1803, and finished in 1822, at an expense of nearly 1,000,000*l.* sterling, entirely defrayed by government. Very great difficulties occurred in its prosecution, from the nature of the ground, and the different levels and currents of the lakes; but all the resources of art were employed by the engineers. As, from circumstances occasioned by the war, wood of sufficient strength could scarcely be procured for the immense gates of the locks,

iron was substituted with success; though the expense of each lock was thus raised to 9000*l*. The locks were twenty-three in all, eight of which, looking down from Loch Eil, where it opens into the western sea, are called by sailors the "stair of Neptune." The canal was made fifty feet broad: its length was about twenty-two miles, which, added to nearly forty miles of lake navigation, made an entire passage of somewhat more than sixty miles. Unfortunately the supposed danger of navigating large vessels through a channel of this peculiar nature has, hitherto, prevented its use from becoming general; but it is hoped that means may be found to remove this apprehension.

SECT. VI. *Civil and Social State.*

2006. *Of the population of Scotland* an estimate was first attempted in the year 1755, when it was computed to be 1,265,380. The reports of the clergy for the "Statistical Account," between 1792 and 1798, gave 1,526,492; which was raised by the government enumeration of 1801 to 1,599,000. The census of 1811 gave 1,805,000; which was raised by that of 1821 to 2,093,456. In 1831, it was 2,363,842.

2007. *In point of disposition*, the Scots are a grave, serious, and reflecting people. Their neighbours remark, at first view, a certain slowness both in words and action; but they soon discover the Scots to be bold, enterprising, ambitious, and imbued with a deep-rooted determination to pursue the objects of their desire, and repel those of their aversion. Under these impulses, they quit, without much regret, a land which affords few opportunities of distinction, and seek, either in the metropolis and commercial towns of England, or in the most distant transmarine regions, that wealth and fame which they eagerly covet; yet, amid this distance and these eager pursuits, their hopes and affections remain fixed on the land of their nativity; they are never naturalised elsewhere, but usually seek to return and spend the evening of their days in Scotland. Thus, they do not readily amalgamate with, or gain the favour of, foreigners with whom they reside, but attach themselves zealously to serve their own emigrant countrymen. The Scots appear naturally brave; a quality which is particularly observable among the highland tribes, and by which they rendered themselves formidable, first under Montrose, and afterwards in the rebellion against the house of Hanover. Since they were conciliated by the wise measures of Pitt, they have crowded into the British army, and formed some of its bravest regiments. The sense of moral obligation appears on the whole stronger among the Scots than among the neighbouring nations. Among the lower classes, crimes against the order of society are of comparatively rare occurrence, and there is less necessity for capital punishment; there is also less of extreme dissoluteness among the higher ranks. Among the Scottish females, in particular, the obligations of the marriage tie are much more seldom disregarded; and if the other sex too often abuse the licence which public manners are supposed to allow, they are at least obliged to observe some outward appearances. It must not be denied that the Scots have their faults. Though the deep potations of their ancestors be now banished from good society, yet they still drink harder than the English, who themselves go farther in this respect than the nations of the south. The pride of birth is still very prevalent, particularly among the highland clans; and it is accompanied with a general ambition to rise above their original station, and a propensity, with that view, to spend their moderate wealth rather in outward show than in solid comfort. The sister nations accuse the Scots as selfish, yet what they experience may, perhaps, be traced rather to the spirit of nationality; for we do not apprehend that Scotsmen raised to power have shown any backwardness, either in the general offices of humanity, or to promote the prosperity of their country and countrymen.

2008. *To their religious duties* the Scots people have always shown an exemplary attention. In catholic times, the Romish church in Scotland enjoyed more influence, and had acquired a much greater proportion of the national wealth, than in England. But when the light of knowledge, which early dawned upon Scotland, had shown the errors of that church, the Scots entered upon the cause of reform with an ardent and thorough-going zeal, which left behind it that of all their neighbours. After a desperate struggle, on which, for nearly a century, the political destinies of the kingdom depended, they obtained their favourite form of presbytery, the most remote from that pompous ritual, for which they have entertained the most rooted abhorrence. The principle of presbytery consists in the complete equality of all its clerical members, who have each a separate parish, of which they perform all the ecclesiastical functions. The title of bishop, so long connected with wealth and power, has been rejected, and that of *minister* substituted. In the management of the poor, and some church functions, the minister is assisted by a body of lay members called *elders*, who constitute the *kirk session*. The government of the church consists in *presbyteries* formed by the meeting of the ministers of a certain district, with lay members from each session, the last of whom, however, attend only occasionally. A *synod* is formed by the union of several presbyteries; and the *General Assembly* is composed of deputies, partly clerical and partly lay, from each presbytery and borough. They meet every year, and an appeal lies to them upon every subject; but the laws of the church, though proposed in the Assembly, can be passed only by a majority of presbyteries, after being debated in each. The king

sends a *Commissioner*, who is present at the debates of the Assembly, and seems even to claim a right of constituting and dissolving it; but this is denied by the church itself, which acknowledges no human head, and accounts itself and the state as powers entirely independent.

2009. *The revenues of the Scottish church* were an object of little concern to the nobility, who showed no want of alacrity in drawing their swords for the cause of the Reformation, and even of presbytery. They availed themselves of the downfall of the catholic establishment, to appropriate nearly the whole of the immense income with which it had been endowed. They took at first not only the lands, but the tithes; and even when obliged to make a provision for the presbyterian clergy out of the latter, they retained part, valued often at a very low rate, but subject to be called upon if needed. Thus the Scots clergy have enjoyed only such incomes as enabled them, with strict economy, to maintain their place in the middle rank of society. When even this became impossible under the increased expense of living, augmentations were granted out of the *tiends*, or valued tithes; and where these were exhausted, the legislature have come forward, and raised the lowest stipend to 150*l.* a year. This moderate income, by withdrawing many temptations to indulge in the vices of the rich, has been supposed favourable to the respectability of the clergy, and to their influence with the people at large. It is generally admitted, that no body of clergy have maintained a fairer character, or more efficiently performed their important duties, than those of the Scottish church.

2010. *The dissenters from the Scottish church* consist chiefly of persons zealously attached to presbytery, and who have *seceded* because they considered its principles as not maintained in sufficient purity within the establishment. Their chief complaint is against the system of patronage exercised by the landed interest, who present generally to the vacant parishes. Two great bodies, into which they were formerly divided on the subject of the burgher oath, have, since the abolition of that test, been united into what is called the *Associate Synod*. A considerable proportion, especially of the higher ranks, is attached to episcopacy, either as it was established in Scotland under the Stuarts, or as it now exists in England; indeed, an union has been recently formed between these once separate branches. None of the other sects, independents, baptists, methodists, &c. are numerous; and the Roman catholics consist chiefly of emigrants from Ireland, though their form of religion still prevails in some of the remote highland districts.

2011. *Literature*, soon after its revival in Europe, was cultivated in Scotland with peculiar ardour. Even in the age of scholastic pursuits, Duns Scotus and Crichton were pre-eminently famed throughout the Continent. When the sounder taste for classical knowledge followed, Buchanan acquired the reputation of writing Latin with greater ease and purity than any modern scholar. Letters were almost entirely suppressed during the subsequent period, unfortunately marked by a conflict between a licentious tyranny and an austere religious party, who condemned or despised the exertions of intellect and the creations of fancy. Even after the settlement at the Revolution the same spirit prevailed; and literature lay dormant till the middle of the last century, when it was revived with extraordinary ardour, chiefly by a class of Scottish clergy, who sought to redeem their fraternity from the charge of ignorance and extravagant zeal. This country, far from opulent, with a church and universities alike poorly endowed, produced as illustrious a constellation of writers as had been called forth by the most lavish patronage in the great European capitals. We shall only mention, in history, Robertson and Hume; in moral and political philosophy, Hume, Reid, Smith, Ferguson, Kames, Stewart, Brown; divinity, Blair, Campbell, Macknight; poetry, Home, Thomson, Beattie, Burns; physical science, Gregory, Black, Playfair, Leslie. The distinguishing character was that of a grave, respectable, and dignified literature, in which the lighter branches were overlooked or despised. If this last was a reproach, it has been wholly removed in the present generation, when the most popular of fictitious writing, and one of the most able and widely circulated periodical works known in modern times, have issued from the Edinburgh press. By the authors of these, and by several others, of the first class in the physical and natural sciences, Scotland continues to make herself and her capital be regarded as a species of literary metropolis.

2012. *The universities of Scotland* have been, perhaps, the most powerful instrument in supporting her literary fame. Though not more richly endowed than the church, the fees of well-attended classes afford a more liberal income, and have enabled them to attract the most learned among the clergy; while, in England, a wealthy church draws eminent scholars from the universities. The Scottish colleges present scarcely any traces of that strict and almost monastic discipline which regulates those of the sister kingdom. The students live generally in the towns, without any check on their private conduct, or even any obligation to attendance, except what arises from the dread of the refusal of a certificate at the close. The chief exertion of the professors is bestowed on their lectures, by which they hope to attract students to their class and seminary. The more diligent combine with them examinations and exercises, but not on the same systematic and searching plan as in England; and the degrees are conferred, in many instances, with culpable laxity. A much greater pro-

portion of the people receive a college education than in England. The church exacts an attendance of eight years; four for languages and philosophy, and four for divinity: the faculty of medicine requires also several years; and the gentry and higher grades of the middle ranks in general consider an attendance on the elementary classes as an essential part of education.

2013. *The public libraries*, when considered in relation to the country, may be accounted rich. That belonging to the advocates or barristers of Edinburgh contains upwards of 100,000 volumes, among which there are ample materials, both printed and in manuscript, for elucidating the national history. The university library is, at least, half as large; and those of Glasgow, King's College Aberdeen, and St. Andrew's, are highly respectable. Each of these universities can claim a copy of every new work. Although the Scots are a writing and reading people, they are not the chief buyers of the works even of their native favourites; nor are there many examples of those magnificent private libraries which enrich so many of the English seats.

2014. *To the fine arts* Scotland has been considered unpropitious; yet painting could early boast the respectable names of Runciman and Jamieson. A considerable time elapsed till Raeburn and Nasmyth rose to eminence in portrait and landscape. In that branch of historical painting which illustrates the habits and feelings of common life, Scotland can boast the greatest name in the present day, that of Wilkie. Even its higher branches have found votaries decidedly successful, though few. Two annual exhibitions, maintained with some interruptions, at Edinburgh, have continued to produce a favourable opinion of the talents of its artists. With the exception of Hamilton Palace, the Scottish seats do not contain grand collections of pictures; yet in this, as in other respects, the taste for the fine arts is making a somewhat rapid progress.

2015. *Scotland has a native music*, simple and pathetic, expressive of rural feelings and emotions, to which she is fondly attached. The ardent cultivators of that beautiful art complain that the passion of the Scots for these national airs shuts their ears against loftier and more varied beauties in the works of Italian and German composers. A sort of musical warfare has been waged; the issue of which has been, that the latter have made their way, though without expelling their domestic rival. The highest strains of Handel, Mozart, and other eminent masters, have been sung to crowded audiences in Edinburgh; while in concerts and private societies, Scottish songs are still listened to with delight. Music, as a branch of education, has certainly been very much extended in Scotland within the last twenty or thirty years.

2016. *The Scots are not a people of pastimes*, nor are their sporting annals so copious as those of the English. Golf and foot-ball are the only amusements that can be deemed strictly national. Skating, and curling, or the rolling of smooth stones upon the ice, are also pursued with great ardour during the season that admits of those amusements. The recreations of the higher ranks are nearly the same as in England. Dancing is practised with peculiar ardour, especially by the Highlanders, who have favourite national steps and movements.

2017. *The lowland dress* has nothing peculiar; though even the poorest ranks are, in general, decently and substantially clothed. The Highlanders, however, retain still the remnants of a national costume altogether peculiar to themselves; the tartan, a mixture of woollen and linen cloth, adorned with brilliant stripes variously crossing each other, and marking the distinctions of the clans; the kilt, or short petticoat, worn by the men, the hose fastened below the knee, which is left bare; and the bonnet, which in another shape is also still worn by the shepherds of the border.

2018. *In regard to food*, the Scots, in general, are temperate. Even the rich attach less importance than their southern neighbours to the gratifications of the palate. The peasantry, previously to the rise of wages, which took place about thirty years ago, were content with the hardest fare. Neither wheaten bread nor animal food formed part of their ordinary diet. Oatmeal, not accounted in the south of England an article of food for human beings, was prepared here under the forms of cakes or porridge, and constituted the chief means of subsistence. To this was occasionally added barley broth, with greens or *kail*, the chief produce of their little gardens. The Scots have some dishes which they cherish with national enthusiasm, and among which the *haggis* holds the foremost place. This is a mixture of oatmeal, fat, liver, and onion, boiled up in the bag which composed the stomach of the animal. They have, moreover, hotch-potch, and other soups, the merit of which has been acknowledged by English palates.

SECT. VII. *Local Geography.*

2019. *The following is a Table of the extent, population, and rental in the different counties of Scotland, derived from agricultural reports and parliamentary returns: —*

Counties.	Square Miles.	Acres under Cultivation.	Rental in 1812.	Houses in 1821.	Population in 1831.	Towns with Population in 1831.
			£

2020. *In treating of Scotland in detail, we shall divide it into its three constituent parts: —*

1. The Lowland counties; 2. The Highland counties; 3. The Islands.

SUBSECT. 1. *The Lowland Counties.*

2021. *The whole of the south of Scotland, though diversified by elevated ranges of hills, is always considered as belonging to the Lowlands. It presents, however, three districts of opposite character: — 1. The agricultural counties along the German Ocean and the Frith of Forth; 2. The southern pastoral counties; 3. The manufacturing counties of the west.*

2022. *The agricultural district of southern Scotland consists of the counties of Berwick (formerly the Merse), of Haddington, Edinburgh, and Linlithgow (fully as familiar under the appellations of East, Mid, and West Lothian), and of Stirling, which touches westward on the highland boundary. Even of this range, the cultivated part is closely hemmed in by Lammermoor, a low, broad, moorish ridge, which fills all the eastern interior of this tract. It reaches even a considerable extent along the shore of the German Ocean, to which it presents the bold promontories of St. Abb's Head and Fast Castle. In Mid Lothian, its highest pinnacle of Soutra nearly locks in with the Pentlands, which are succeeded to the westward by a long bleak table land reaching as far as Glasgow, and reducing to the breadth of a few miles the beautiful carse of Falkirk and Stirling.*

2023. *The cultivated part of Berwickshire consists of the Merse, extending chiefly along the Tweed, and reaching to the sea. Its improvement, though scarcely commenced half a century ago, has been carried on with the greatest industry, and there is no part of Scotland which can boast of more skilful and prosperous farmers. Above it is Lauderdale, or the Valley of the Lauder, which is fitted chiefly for grazing, and touches closely on the heaths of Lammermoor.*

2024. *Berwick, by position as well as name, belongs naturally to this county, though after a long series of bloody contests for its possession, James VI. declared it neutral ground, and Great Britain cannot now be fully designated but by calling it England, Scotland, and Berwick upon Tweed. This town has a district attached to it of about 5000 acres, called "Berwick bounds." Though the harbour be indifferent, and liable to frequent injury from the action of the river, yet, as the Tweed here receives large vessels, Berwick is the chief channel for exporting the valuable produce of the Merse, to the annual amount, it is said, of 80,000 bolls of grain. A quantity of the Tweed salmon, preserved in ice, is also sent to the London market. The strong wall and deep ditch, which once defended Berwick, still remain, though neglected; and large barracks have been erected.*

2025. *Of the towns in Berwickshire*, Greenlaw is the seat of county business, though it and Lauder, the only borough, are but small places in the upper district. Dunse, in the heart of the agricultural tract, is the most thriving and prosperous. Coldstream, a large pleasant village on the banks of the Tweed, is noted as the scene of Monk's retirement. Eyemuth is a small seaport, where there is some fishery.

2026. *Haddingtonshire, or East Lothian*, runs along the mouth of the Frith of Forth, between which and the range of Lammermoor extends a plain about twenty miles in length and twelve in breadth, perhaps the largest in Scotland, and all under high cultivation. The East Lothian farmers are considered as thoroughly acquainted with the science of agriculture, and practically skilled in its most improved processes. Some of them have made considerable fortunes; though the rise of rents, and subsequently the fall of prices, have caused a certain reverse in this particular. Grain and artificial grasses of every description are raised in perfection; scarcely a spot, unless on pleasure grounds, being left under natural grass. Edinburgh is chiefly supplied with wheat from the market at Haddington, which is considered one of the first in the country.

2027. *The towns in East Lothian*, which is in no degree a manufacturing county, are of secondary importance. Haddington is neat and pleasant, supported only by the market and by its court for legal proceedings. Dunbar has a little trade and fishery. Its castle, the ruins of which extend over a promontory of broken rocks, stretching out into the sea, forms a truly grand object. North Berwick, though a royal burgh, is, in fact, only a pleasant village, near the foot of the insulated eminence, or *law*, which bears its name. Opposite is a range of rocky islets, of which the most remarkable is the Bass, "that sea rock immense," the steep sides of which rise to the height of 400 feet. The side facing the ocean forms a perpendicular precipice, on which build crowds of that rare species of sea-fowl called Solan goose. Their young, whose down is of some value, are taken by the perilous exertions of fishermen, suspended by ropes from the top of the cliff. There are still some remains of the fortified prison which was in ancient times reserved for state offenders, and in which some of the most eminent covenanters were confined for several years. On the shore immediately opposite, crowning a perpendicular cliff, appears Tantallon, a strong castle of the Douglasses, now in a ruinous state, and bearing marks of exchanges of artillery with the Bass, while the latter was in possession of the English. Prestonpans, a long dirty village, has some manufactures of salt and vitriol.

2028. *Mid Lothian, or Edinburghshire*, the next in order, is the metropolitan county of Scotland. The same system of agriculture prevails here as in East Lothian; and some of the fields, copiously supplied with manure from the capital, bear very heavy crops. On the whole, however, this county does not afford the same extent of surface fit for the plough. It is penetrated by a branch of the Lammermoor, and by the long range of the Pentlands: and at the distance of a few miles south from Edinburgh, a general high level begins, which is favourable only to the production of oats and barley. A great part of this county is laid out in garden ground for the supply of the metropolis, in nursery grounds, and in potato fields. There are no manufactures of any consequence, the county being entirely supported by the metropolis and its appendages.

2029. *Edinburgh*, the capital of Scotland (*fig. 189.*), is a city of no very high antiquity. The Castle Hill, indeed, whose rocky and precipitous sides support on the summit a level space

189

EDINBURGH.

of some extent, accessible only by a narrow ridge at one point, must always have been of importance in a military age. It is named in the Pictish annals under the title of *Castrum Puellarum*, which is supposed to have originated from the custom of placing the princesses and ladies of rank to be educated there, as in a place of security. In the tenth century, mention is first made of the town of *Edin*; but David I., in the twelfth century, founded the abbey and palace of Holyrood; and, under the sway of the Stuarts, Edinburgh became gradually the undisputed capital of Scotland.

2030. *Edinburgh* is built upon three ridges, running from east to west, and separate from

each other by deep ravines. The Old Town, which, till the last half century, formed the whole of Edinburgh, is situated on the middle ridge, extending nearly a mile of gradual descent from the Castle to the palace of Holyrood. With a view to secure the protection afforded by this site, the houses have been crowded into the very smallest possible space; they are raised six or seven stories on the side facing the street, which from the acclivity of the ground, gives to that facing the ravine a height of ten or even fourteen stories. From this central street, there descend on each side *closes* or lanes about six feet broad, and sloping often at an angle of forty-five degrees, so that some experience is required to descend with safety. The Cowgate, a poor street, inhabited by small tradesmen, extends along the bottom of the ravine, and terminates in a spacious *Grass-market*, completing old Edinburgh. Although it contains many excellent houses, it is now entirely deserted, unless by the inferior orders of tradesmen, who occupy spacious apartments, at very low rents. All the citizens of better rank have migrated to two towns, built on the opposite sides of the Old Town; one on the south side, or St. Leonard's Hill, occupied by citizens of the middle class, those connected with the university, or such as are fond of retirement: the other, called properly the New Town, is on the north; and at present comprises the residence of almost all the opulent and fashionable classes. Being built on a regular, perhaps somewhat too uniform plan, and of the fine freestone found in Craigleith and other neighbouring quarries, it ranks, generally, as one of the most elegant towns in Britain. Extensive improvements are now in progress; one consisting of a new bridge, between the Old Town and the southern districts, and the other of a south-west approach, carried along the lower declivity of the Castle Hill. The inhabitants, however, who defray the expense by an assessment on the house rents, have begun to complain heavily of the amount far exceeding the estimate of the sum required to complete these works.

2031. *The beauty of Edinburgh* is greatly enhanced by its situation; being overlooked on one side by the proud eminence of the Castle, and its fine ancient towers, though somewhat marred by modern additions; and on the other, by a range of bold hills, the highest of which is called Arthur's Seat. The lowest, the Calton Hill, round which walks of easy access have been formed, commands a view of Edinburgh, the Frith of Forth, and its surrounding shores, which attracts the admiration of every stranger.

2032. *The general effect*, rather than that of any particular edifices, constitutes the merit of Edinburgh. Of antique structures, there is nothing very fine, except the large hospital for boys, erected from the funds bequeathed by George Heriot, the celebrated goldsmith. The great cathedral of St. Giles has been admired almost solely for its spire, and Holyrood Palace, a comparatively modern structure, for its little ancient chapel. The former, however, has been now externally rebuilt on a very handsome plan, and the latter has undergone a thorough repair. Four miles south, in a very commanding situation, are the remains of Queen Mary's pleasant country palace of Craigmillar. The Register Office is an elegant and classic edifice. Forty years ago, a new college was undertaken by national subscription, and a noble front was erected on the design of Mr. Adam; but the funds being exhausted, it remained long in a state almost of ruin, nearly concealed from view by a street of shops run up immediately opposite. In this exigency, government liberally came forward with an annual vote of 10,000*l.*, to be continued till its completion, which is now nearly effected, under Mr. Playfair's judicious modification of the original design. The new High School is an extremely elegant structure; but the National Monument, on the Calton Hill, begun on the model of the Parthenon, is stopped for want of funds.

2033. *Few cities have increased more rapidly* than Edinburgh, both in extent and population. Its inhabitants in 1801, including Leith, were 82,560; in 1831, they had increased to 162,156. The principal support is derived from the law, to which belong judges, to the number of about 20; advocates 500; writers to the signet 700; and a variety of inferior practitioners. The professors of the university, and private lecturers, &c. constitute a considerable number; and genteel families are attracted from every part of Scotland by the opportunities of education and agreeable society.

2034. *Edinburgh is a city eminently scientific and literary*, and has even become known under the appellation of the "modern Athens." Connected with these pursuits, an extensive trade in printing and publishing books is carried on by some enterprising individuals.

2035. *There are few manufactures*, with the above exception. A great quantity of ale is brewed, which has attained to a high reputation; and there are in the neighbourhood some considerable distilleries. Shawls are manufactured equal, if not superior, to any in the empire. There are very extensive banking establishments, both public and private, and considerable fortunes have been made in that branch of commerce.

2036. *The University of Edinburgh*, founded in 1581, has risen to great fame, both as an institution for teaching, and a nursery for eminent men. The medical school, in particular, attracts students from all the three kingdoms; and the degree of M. D., bestowed here after strict examination, is reckoned to confer peculiar distinction. Debating societies, formed among the students themselves, have been the means of eliciting much talent. The annual

number of students at the university now rather exceeds 2000. They are lodged in the town, and are not subject to any personal discipline, except that of attendance on the lectures. Edinburgh has its Royal Society for physical and literary researches, its Antiquarian and Horticultural Societies, an Institution for the promotion of the Fine Arts, and an Academy for Painting.

2037. *Leith is the port of Edinburgh*, and carries on a considerable import trade for the supply of that capital and of all the interior country. During the last war, the trade of Leith rose to a high pitch of prosperity; but some unfortunate reverses after its close caused the failure of several of the first houses, and threw the town into a languid state, from which it is but very gradually reviving. Her trade is chiefly with a view to the supply of the capital, for which purpose she carries on a constant intercourse with London and other ports on the eastern coast. Her intercourse with the Baltic is very extensive; and that with the West Indies considerable, though not equal to what is carried on from the Clyde. The harbour of Leith is formed by the small river of the same name, coming down from the western side of the Pentlands, passing on the north of Edinburgh, and dividing the town itself into North and South Leith; the latter of which is the larger division. The harbour is not good; but the town of Edinburgh, which possesses a municipal jurisdiction over Leith, has expended very large sums in the construction of an extensive range of docks for the accommodation of its shipping; and a pier, which, stretching far into the sea, so as to enable vessels to enter at all times of the tide, with a breakwater opposite, has been lately completed. The roads, at the distance of about a mile, afford excellent anchorage. Leith, originally a collection of rather ugly and dirty lanes, is now everywhere skirted by excellent streets, and ranges of villas, erected by the opulent inhabitants for their private residence. In 1832 there entered its port 334 vessels, tonnage 46,200.

2038. *Besides these great towns, Mid Lothian contains only some large pleasant villages.* Portobello, is the principal bathing place of Edinburgh. Musselburgh, Fisherrow, Inveresk, are clustered together near the mouth of the Esk, the scene of the battle of Pinkey. Musselburgh has now a good turf, which has supplanted Leith sands for the annual Edinburgh races. Dalkeith, an agreeable rural little town, has the best oat market in Scotland. The valley of the Esk hence upwards to Roslin contains the finest scenery in the Lothians. The lofty banks on each side, either overhung by vast woods, broken into steep precipices, or opening into romantic dells, present continual change of prospect. Roslin chapel, though not on an extensive scale, exhibits some exquisite specimens of Gothic sculpture; and the ruins of the castle bear marks of great strength. On a precipice, rising above the river, stands Hawthornden, an edifice not corresponding to its site; but the votary of the muse, seated in the chair of Drummond, must feel no common emotion on beholding the same scene of the Esk rolling through finely wooded banks, on which the poet's eye reposed. All the south and west of this county consists of wild, hilly, and pastoral scenery, in the heart of which is a pleasingly retired spot, chosen by Ramsay as the scene of his *Gentle Shepherd*.

2039. *Linlithgow or West Lothian* consists, in its upper part, of a bleak table-land; in its lower, of an extensive plain, beautiful and fertile, which the farmers cultivate with all the skill and success peculiar to the best parts of Scotland. It abounds with coal, freestone, lime, and marl. There are no manufactures of any consequence. The Union Canal passing through this county has afforded an improved conveyance for its mineral and agricultural produce.

2040. *The towns in this county* are small; but Linlithgow retains still somewhat of the

LINLITHGOW PALACE.

aspect of grandeur suited to a once royal residence. The palace (*fig. 190.*), situated on a hill behind the town, and overlooking a beautiful little lake, forms one of the grandest ancient edifices in the kingdom. There is also a Gothic church of some beauty. Borrowstownness, often abridged Bo'ness, once carried on all the trade of the upper Forth; but

the great canal terminating at Grangemouth has now attracted the larger proportion of it to that port. Queensferry is a pleasantly situated village, at which is the main passage across the Forth.

2041. *Stirling*, an extensive and beautiful county, the link between the Highlands and Lowlands, extends for thirty-five miles along the Forth, which, in the course of that space, passes from a river into a frith. Few counties present a greater variety of soil and surface; it encloses several of the richest *carses* in Scotland; but the greater part is hilly and pastoral, while many of the lower grounds consist of fine meadows, adorned by the beautiful meanderings of the Forth. It even encroaches on the Highlands, since its western extremity includes Ben Lomond. This county is traversed by the celebrated Roman wall between the Forth and Clyde, usually ascribed to Antoninus, though from the account of Tacitus it would appear to have been first formed by Agricola. It seems to have reached from near the church of Old Kilpatrick, about four miles above Dumbarton, to Carriden, near Bo'ness, rather more than thirty-six miles. Stirling is also crossed by another feature as grand, and more useful, — the great canal between the Forth and Clyde.

2042. *The town of Stirling* can boast a situation as noble and commanding as any in Scotland. The view from its castle, which includes entire the principal range of the Grampians, the meadows or links through which the Forth winds, and a part of thirteen counties, is generally considered the finest in the country. The main street, like that of Edinburgh, descends gradually down the ridge of the hill on which the castle stands (*fig. 191*). This fortress, in feudal times, was accounted one of the bulwarks of the kingdom; and

191

STIRLING CASTLE.

Stirling was the frequent seat of royalty, and the scene of many of the most memorable and tragic events in Scottish history. The town has now lost this distinction, and owes its present limited prosperity chiefly to its position on the main land route into the Highlands, and to some spirited attempts to introduce the carpet manufacture and other branches of industry. Falkirk is a larger town, situated in a broad and beautiful *carse*, through which the Forth flows like a broad river, backed by the considerable range of the Ochils. The three great annual *trysts* exhibit an immense show of highland cattle and sheep brought up for the supply of the southern districts. Near Falkirk is Carron, accounted only a village, but the seat of the greatest iron-works in Scotland, in which, during war, 2000 men were employed. It particularly excels in grates, and in that species of artillery first cast here, and hence denominated carronades. Grangemouth, at the connecting point of the great canal with the Frith of Forth, derives from this situation a considerable trade.

2043. *The seats in the great agricultural district* now surveyed are numerous and handsome, though few are on a very great scale. At the western extremity of Berwick, Lord Buchan has Dryburgh Abbey, a beautiful Gothic edifice, of great antiquity. The late Earl of Wemyss built in East Lothian Amisfield and Gosford, the latter on the coast of the Forth, and of great extent, but now used only as a gallery for containing an extensive collection of pictures, some of which are very fine. In Mid Lothian, Dalkeith House aspires to the name of palace, chiefly in consequence of the great extent of beautiful grounds and lawns that surround it. The Marquess of Lothian's seat of Newbattle Abbey is surrounded by noble trees. The beauty of its site, and its ceilings painted by Runciman, give merited celebrity to Pennycuik House. In West Lothian, Hopetoun House is a truly superb mansion, overlooking a spacious lawn which slopes down to the Forth. Dalmeny Castle has also a great extent of finely wooded grounds extending for several miles along the coast. In Stirlingshire, Callender House is a fine seat, including most of the country round Falkirk. Craigforth is happily situated on a cliff above the river, at the point where its windings are the most varied and beautiful. On the western border, the Duke of Montrose has the beautiful seat of Buchanan, near the banks of Loch Lomond, and on the immediate brink of the Highlands.

2044. *The next district, including the counties of Roxburgh, Selkirk, Peebles, Dumfries, and part of Lanark*, may most properly bear the appellation of pastoral Scotland. It is covered with long ranges of hills, not in general heathy or rugged like those of the Highlands; but from one to two thousand feet high, clothed with pasturage to their summits. This may be justly held the region of Scottish poetry. The events of border war and feud, which kept it for ages in perpetual excitation and alarm, gave birth to strong feelings and passions, and inspired strains which are still fondly recited. To these succeeded love songs dictated by nature, and often inspired by refined feelings. It was amid these scenes that Thomson and Scott caught that inspiration which has rendered their poetry the delight of their country. The chief occupation in all this tract is sheep-farming; only detached districts being fit for the plough, or having meadows sufficiently rich for rearing cattle of a large breed; and there are scarcely any traces of manufacturing industry.

2045. *The towns in this tract* are generally small and agreeable. Kelso is considered one of the most beautiful in Scotland, being surrounded by ornamented villas and extensive woods, which cause it almost to resemble a town in the south of England. The abbey is not without some grandeur; and the ruins of the castle of Roxburgh are striking. Kelso has a gay and literary circle of society. Hawick is a tolerably sized country town, pleasantly surrounded by hills, and has a little carpet manufactory. The village of Melrose is only distinguished by its abbey (*fig. 192*), founded by David I., in the twelfth century, and the finest edifice ever

192

MELROSE ABBEY.

erected in the south of Scotland. All the elegance of that architecture which we call Gothic has been lavished on this pile, and is displayed in the profusion of the ornaments, and the beauty of the sculptures, which remain nearly entire, and have rendered it the study of the painter and the theme of the poet. Selkirk and Peebles, capitals of their respective little counties, are only pleasant villages, bordering on the great pastoral vales of Etterick and Yarrow. These do not contain even a village; and on the western side of them we enter Dumfries-shire, and find Moffat, a small town in a picturesque site amid rocky hills, and containing a mineral spring of some repute. Proceeding southwards, we discover on the shores of the Solway the principal towns of the county:

Dumfries itself, a well-built, gay-looking city, is a sort of southern Scottish capital, and it has been so distinguished from an early period; but no traces remain either of the castle, or of the monastery in which Cumming fell by the hand of Bruce. To the west and south, the country is fine, watered by the Nith and other rivers; but to the east, there are only the vast mosses of the Solway. The town carries on some trade by the Nith, which admits vessels of one hundred and twenty tons, and it has two great annual markets for the cattle from the west; but it is chiefly supported by the many neighbouring gentry who make it their residence. Annan is agreeably situated at the mouth of the river of that name. Lochmaben, ancient, and distinguished by

the ruins of a strong castle, Thornhill and Sanquhar on the upper course of the Nith; Langholm, in the centre of the pastoral vales of the Esk and the Liddle; may all rank as little towns or large villages. A small spot, famed in the annals of gallantry, is Gretna Green, close on the English border; whither fly many a fond matrimonial pair, to escape the jealousy of parents and guardians, and avail themselves of the dangerous facility of Scottish marriage. On the bleak northern boundary, and on an almost mountainous level, is Wanlockhead; and nearly contiguous to it Leadhills, in Lanarkshire. Wanlockhead belongs to the Duke of Buccleugh, and yields annually lead to the amount of about 15,000 bars, of nine stones each; while Leadhills, belonging to the Earl of Hopetoun, yields about 18,000. The workmen form a little society, distinguished for order and good conduct, and support among themselves a small subscription library.

DRUMLANRIG CASTLE.

Abbotsford, from the many additions made by its illustrious proprietor, has become a striking and picturesque object.

2047. *The three counties of Ayr, Wigton, and Galloway* compose what has been specially called the West of Scotland. Like the southern counties, they are chiefly under pasture; but the cultivators are much less occupied in the breeding of sheep than in the rearing of cattle. The surface is very various. The range of mountains, indeed, which separates Ayr and Galloway is almost as elevated as any in Scotland; but the upland country of the latter is, in general, diversified only with steep rocky eminences of two or three hundred feet high. In Ayr, too, though the southern district of Carrick be very mountainous, the middle one of Kyle has a level coast; while Cunningham, the most northerly, consists almost entirely of a fertile plain. Both counties, from the boundary line of mountains, are watered by fine rivers; in one, the Ayr, the Doon, and the Irvine; in the other, the Dee and the Cree. The Ayrshire breed of horses, called also the Clydesdale, is highly esteemed; and generally supplies the markets in the east of Scotland; but the little active breed called galloways are now become scarce. It is in horned cattle that both districts place their chief boast. The kine of Ayrshire are valued chiefly for the dairy, which produces the only cheeses in Scotland that have acquired celebrity. The Galloway bullock without horns produces beef of a peculiar excellence, which often reaches the London market. In general, though the farmers have quitted their alternation of three arable crops for six of pasture, and have adopted some modern improvements, their agriculture is much behind that in the Lothians; the farms are small, and have little capital vested in them. The northern division of Ayr, where it borders on Lanarkshire, participates to a certain extent in the flourishing manufactures of that great county. It has also an extensive iron-work at Muirkirk, and immense beds of valuable coal, which not only serve for the supply of the inhabitants, but are exported to Ireland in such quantities as to form the chief trade of this county. To facilitate the transport, the Duke of Portland has formed a fine harbour at Troon, and has connected it by a railroad with Kilmarnock. A still grander project was that of Lord Eglinton, who undertook to form a harbour at Ardrossan, which would have been one of the finest in the west of Scotland; and to connect it with Glasgow by a canal. Ardrossan, as the port of Glasgow, would then, probably, have superseded Greenock, since it would have allowed vessels to enter at once upon the open sea without passing the winding channels of the Frith of Clyde. The difficulties of the times, however, and the prior establishment of Greenock and Port Glasgow, were unfavourable to this project; only a third part of the canal was completed, and the whole design is now relinquished.

2048. *There are several considerable towns in Ayrshire.* Ayr, at the point where the rivers Doon and Ayr fall united into the sea, is a gay place, forming a sort of capital for the gentry of a considerable part of Scotland. In ancient times it was still more important, as the principal scene of some great historical events in the time of Wallace and Bruce; and, at a much later period, as an important military station, having been carefully fortified by Oliver Cromwell. Its trade, also, was greater, rivalling that of the ports on the Clyde; but the bar at the mouth of the harbour, completely obstructing the entrance of the Doon, has been unfavourable to its progress. It exports, however, chiefly to Ireland, a considerable quantity of coal, brought by railways. The town is irregularly built, but has one handsome principal street. Its theatre, its academy, and some charitable institutions, are on a greater scale than the size of the town might lead us to expect. Proceeding northwards from Ayr, occur the ports of Troon, Irvine, Saltcoats, and Ardrossan, which send large quantities of coal to Ireland; whence they receive grain for the supply of the great interior towns. Saltcoats, which has sprung up within the last century, is also noted for the manufacture of salt; and Ardrossan is now a watering place of increasing resort. The same may be said of Largs, the celebrated scene of the defeat of Haco, the last Danish invader, after a sanguinary conflict; memorials of which are still occasionally dug up: though only a village, it attracts many visitors by the extreme beauty of its situation. In the interior of Ayrshire is Kilmarnock, its largest and most thriving town. The manufacture of various woollen stuffs, carpets, caps, serges, tartans, saddlery, and other fabrics of leather; and latterly branches of the cotton weaving from Glasgow, place it high in the list of Scottish manufacturing towns. Kilwinning, a small and decayed place, is celebrated in the annals of freemasonry, for the first introduction of that mystery into Scotland, in the twelfth century; at which period was erected the extensive monastery, of which only a few fragments remain. Cotton spinning is carried on to a considerable extent at Catrine, a large village, founded by Mr. Dale.

2046. *Seats.* A vast extent of those pastoral regions belong to the now united houses of Buccleugh and Queensberry. The Duke has numerous seats in the district, of which the chief is Drumlanrig Castle (fig. 193.), a magnificent edifice, on an eminence above the Nith, and surrounded by extensive parks and plantations. At the mouth of the Nith is Caerlaverock Castle, long the seat of the Maxwell family, now only an extensive and picturesque ruin. Among many others round Kelso, is Fleurs, the splendid seat of the Roxburgh family. Minto House, near Kelso, is surrounded by fine grounds, to which a range of lofty perpendicular crags gives a grand character.

Dunlop is merely a hilly district, with rich pasture, where the cheese of that name, the best in Scotland, is produced. In the south Maybole, Girvan, and Ballintrae are only villages.

2049. *Galloway is almost entirely a rural district.* Its capitals, Wigton and Kirkcudbright, are pleasant country towns, and the latter, having a good harbour, has, of late, considerably increased. Stranraer also is a port of some little consequence. A more conspicuous rank is held by Portpatrick, the nearest point of Great Britain to the Irish coast, whence it is only twenty-one miles distant. It has thus become the main channel of communication between Scotland and Ireland; for which purpose an improved harbour has lately been constructed at a very great expense, and regular packet boats are established. Near Portpatrick, the ruined castle of Dunskey, situated on a high cliff, overlooks the Irish Sea.

2050. *In the counties of Lanark and Renfrew we contemplate a scene very different from that which has now been surveyed.* They constitute the valley of the Clyde, the grand theatre of Scottish commerce and industry. Yet it must be premised that Lanarkshire, or Clydesdale, is divided into three regions, of widely different character. The upper valley, from the place where the Clyde issues out of a steep and high chain of hills to that where it encircles the broad base of Tinto, is altogether a rude pastoral region, similar to the parallel valley of the upper Tweed. Below Tinto, and near Lanark and Hamilton, the banks of the Clyde assume a softer and gayer character. Between these towns they exhibit a variety of beautiful scenery, formed by the falls of the river, and by a succession of gardens and orchards; this being the only part of Scotland where the cultivation of fruit is practised as a branch of husbandry. Below Hamilton comes the district around Glasgow, which is flat, and has not much of variety or beauty, but it supplies that great city with inexhaustible stores of excellent coal. Next to Glasgow is Renfrewshire, in its passage along which the Clyde gradually expands into a broad frith bearing fleets of merchant vessels on its bosom; and at its mouth are the leading and only great ports of the west of Scotland. In the interior are several flourishing manufacturing towns, among which Paisley stands pre-eminent.

2051. *Glasgow is the pride of Lanarkshire,* the commercial capital of Scotland, and in population the third town in the island. It is ancient, tradition ascribing its origin and erection into a bishopric to St. Mungo, in the year 560. The cathedral was then commenced, and, in 1123, assistance towards its erection was obtained from various parts of the country; yet in 1560 the population did not exceed 4500. A century after, it had advanced to 12,000; and in the disturbances during the reign of Charles II. we find it ranking as the capital of the west. Its rapid rise to greatness, however, commenced with the union, which opened to it the trade with America and the West Indies, hitherto monopolised by the English ports. In 1718, for the first time, a vessel from the Clyde sailed across the Atlantic. By the middle of the century, the merchants of Glasgow carried on an active trade with Virginia and Maryland, then the richest of the American colonies. They imported more than half the entire amount of tobacco which came into Great Britain; and to them the French farmers-general chiefly looked for their supply of this important article. The trade of Glasgow appeared likely to suffer from the American war, and the independence of the United States, which enabled the latter to send the produce of their plantations direct to France. The merchants of that town, however, soon showed that they possessed all the energy necessary to redeem these losses. In New England and the other northern states they found an ample vent for their manufactures; for the sale of which commission houses were opened in all the principal towns. Their intercourse also with the West Indies, which had hitherto been very limited, was now carried on to a vast extent. In 1775, there were imported thence 4600 hogsheads of sugar, and 1150 puncheons of rum; in 1814, 40,000 hogsheads and 12,000 puncheons.

A still greater source of wealth was opened at home. Glasgow had, in the course of the century, become a great manufacturing city, employing her industry on the old staple of linen of the finer descriptions, as cambrics, lawns, gauzes, also in the making of stockings and of shoes for exportation ; but its product in these branches never exceeded 400,000*l*. Affairs were conducted on a very different scale when cotton was extensively introduced into Britain ; and Glasgow, soon relinquishing her former occupations, devoted herself entirely to this new manufacture. She became the rival of Manchester ; and, if circumstances did not allow her to obtain so great a share of the manufacture, she produced some finer fabrics, and was as prompt in availing herself of every improved process. Scotland was soon astonished by the magnitude and power of the machines constructed ; immense fortunes were realised, and an annual value of nearly 4,000,000*l*. sterling produced. Glasgow was one of the first places which adopted the invention of power looms, in which weaving is performed by machinery, and she has now 10,000 of these, and 32,000 worked by the hand. She felt, after the peace of 1815, the effects of a reduced and precarious demand in the markets both at home and abroad. But, on the whole, her prosperity and population have continued to increase ; and it deserves mention, that the consumption of butcher's meat, as compared with the population, nearly equals that of London ; that in 1830 the number of persons receiving parochial aid was only 5000, not quite one fortieth part of the inhabitants, and that the sum expended on the poor was only 17,287*l*. Glasgow is now the largest town, not only in Scotland, but in Great Britain ; London and Manchester excepted. The harbour is at the Broomielaw, where there is an extensive quay along the Clyde ; but so great were the obstructions to its navigation, that Glasgow, according to Pennant, was " completely tantalised by its river." From the year 1556, attempts were made to improve it, but with inadequate skill and means. At length, in 1770, Mr. Golburn, an engineer of Chester, succeeded in removing the sand-banks to such an extent that vessels of 150 tons now come up with ease. Still Glasgow suffers from this cause, and depends chiefly for imports on Greenock and Liverpool. In 1832 there entered its port only 79 vessels, of 8154 tons. Glasgow is, on the whole, a handsome and well-built town. Its original streets of Argyle and Trongate are broad and spacious, superior to the Old Town of Edinburgh, though it can produce nothing to rival the New Town. Several handsome squares have been built within the limits of the city ; but the fashionable residences are now almost exclusively in the west, where, along a range of somewhat elevated ground, a number of most elegant and spacious streets have been erected, terminating with Blythswood Square. Gorbals, Calton, Bridgeton, Hutchesontown, Tradeston, and Anderston, are the principal suburbs, and form

the manufacturing part of the city. The public edifices deserve admiration. The cathedral (*fig.* 194.) is one of the finest in Scotland ; not as a specimen of the light and ornamental Gothic, but as a massive structure, producing a powerful and solemn effect, much heightened by its striking insulated situation, with a wooded hill closely adjoining, on the top of which a monument has recently been erected to the memory of John Knox. The modern edifices are also handsome, and designed by the best architects : the Lunatic Asylum, and a building containing the court-houses and prison, by Mr. Stark ; the Assembly-rooms and the

194

GLASGOW CATHEDRAL.

Infirmary, by Mr. Adams ; the spacious Roman catholic chapel, a fine specimen of the modern Gothic, by Mr. Gillespie. The very elegant theatre was some years ago burned to the ground ; but the new Exchange Reading-rooms, recently erected, form one of the most splendid edifices in the country. The bridewell for the county and city has been erected on the most approved principle, and is esteemed the most perfect in Scotland, both in point of construction and management. Glasgow is not a mere commercial town ; its university is an interesting and distinguished establishment. Founded in 1450 by Bishop Turnbull, it has been adorned by a long succession of illustrious teachers, of whom Simson, Hutcheson, Reid, Smith, Millar, would be alone sufficient to ensure its celebrity. It is at present attended

by 1400 students, and its name stands at least as high as at any former period. The edifice has nothing striking; but with the houses of the professors, built in a square attached to it, forms an extensive range. The library contains 30,000 volumes, many of which are valuable, and even rare. A splendid bequest was made some years ago, in the Museum formed by the late Dr. Hunter, particularly rich in anatomical preparations, shells, insects, fossils, as well as in coins and medals, the collection of which is considered the most complete in Europe. An elegant Grecian edifice, designed by Stark, has been erected for their reception. Auxiliary to the University is the Andersonian Institution, founded with the view of communicating to the commercial classes a knowledge of the first elements of physical science; for which purpose it has been found highly efficacious. The intellectual spirit of the citizens is also proved by three libraries, and a botanic garden, all supported by public subscription.

2053. *Paisley*, though in Renfrewshire, may be considered next, in order to connect together the great seats of manufacture. This town is also ancient, deriving its distinction from its ecclesiastical character. The abbey, founded in 1160, was gradually enriched, having much landed property attached to it, and drawing the tithes of twenty-eight different parishes. At the end of the fifteenth century, many ornaments were added; but soon after occurred the Reformation, in consequence of which the edifice was in a great measure demolished, and the revenues converted into a temporal lordship, in favour of a son of the Duke of Chatelherault. Several of the windows, however, still afford fine specimens of the ornamented Gothic; and, at the Reformation, the nave was left so far entire that it has ever since served as a place of worship, and is now called the Abbey Church. Yet, amid the lustre derived from this establishment, Paisley was a very small town until the middle of the last century, when it contained little more than 4000 inhabitants. Soon after, its manufactures, which were already begun, made most rapid advances. Down to the year 1783, they consisted chiefly of linen, fine thread, gauzes, both of linen and silk, and other delicate and elegant fabrics. On the introduction of cotton, the manufacturers of Paisley, like those of Glasgow, cultivated this branch almost exclusively, preferring its most elegant species. Muslin, the finest of all the productions of the loom, became the staple of Paisley. In 1805, there were 20,500 persons employed in weaving muslin, 7000 in spinning, and 2000 in other branches; the entire produce of whose labours was rated, we should suppose, too low at 1,250,000*l*. Since that time, the population having increased one half, the productive industry has not, probably, advanced in a less proportion. By the improved navigation of the river Cart, and by means of a small canal where that improvement was impracticable, this town has now a communication with the Clyde, receiving vessels of forty tons. The canal from Glasgow likewise, destined for Ardrossan, has been carried as far as Paisley. These communications have been of great use for the disposal of its produce; but it has remained always a purely manufacturing town. It is divided into two parts, the old and the new; the former on the western and the other on the eastern side of the river Cart. Yet, even of what is termed the old town, the greater part has been recently built on a regular plan, and contains many good houses. The county gaol and bridewell form one of the finest structures of the kind in the kingdom; the town-hall and several of the churches are very handsome. The operative weavers of Paisley are reported to be equal, if not superior, in intelligence to any class of the same rank elsewhere; and this spirit has led to the formation among them of a number of book societies, reading rooms, and subscription libraries.

2054. *Greenock* is entirely a commercial and maritime station; it is the only great western port of Scotland, and ranks somewhat superior to any on the east coast. At the beginning of the last century it was only an inconsiderable fishing village. The commerce with the colonies, for which alone it was happily situated, was then still monopolised by England. Even after the union had removed this barrier, the commerce of Greenock was connected with and dependent on that of Glasgow, the merchants of which were the proprietors of almost all the vessels in its port. By degrees the energy and enterprise of the natives of Greenock enabled them to form a shipping interest of their own; and the same may be said of their commercial undertakings. Still, by far the larger proportion of the vessels belong to Glasgow. The principal trade consists in importing the produce of the West Indies, to which is added a very extensive herring fishery, and a considerable share of the cod fisheries of Newfoundland and Cape Breton. The sum of 90,000*l*. has been lately expended in the improvement of the harbour, which can now contain 500 sail. A very handsome custom-house, facing the river and the quay, has been lately built by government. In 1832 there entered its port 282 vessels, tonnage 78,131. Greenock is not an elegant town; but the hills behind it command a noble view of the river, the shipping, and the vast range of the mountains of Argyle on the opposite coast.

2055. *Port Glasgow*, about three miles higher than Greenock, and a much smaller port, continues subservient to Glasgow, receiving such vessels belonging to that city as are too bulky to ascend the Clyde: in this capacity, its trade is very considerable. Here was built the first dock in Scotland, in front of which a

spacious quay extends along the Clyde, for the accommodation of those vessels which do not require to enter the basin. The environs of Port Glasgow are singularly picturesque and agreeable. Little can be said of Renfrew, the nominal capital of this flourishing county: it is an old town, which has not shared in the prosperity of its neighbours. The inhabitants, however, receive a little employment from the manufacturers of Glasgow.

2056. *The banks of the Clyde above Glasgow*, whose vicinity forms only a small part, however important, of the extensive county of Lanark, are still to be surveyed.

BOTHWELL CASTLE.

First occurs Bothwell (*fig. 195.*), one of the principal seats of the Douglasses. Here Edward I. placed the chief garrison, which was intended to hold Scotland in subjection. It is now a bold and striking ruin, rising above the river banks. A little above is Bothwell Bridge, so noted as the disastrous scene of the rout of the covenanting army. Farther up is Hamilton, a pleasant handsome town in a fine country: it is supported by the residence of the family of Hamilton, and by a branch of the cotton manufacture. From Hamilton the road leads through a range of orchards, and the most beautiful scenery, to Lanark. This town, though bearing the name of the county, is only a large straggling village; but about a mile distant is New Lanark, noted for the extensive cotton manufactory established by the late Mr. Dale, and lately conducted by Mr. Owen. Whatever may be thought of the speculative tenets of the latter gentleman, the attention paid to the behaviour and comforts of those employed presented, certainly, in many respects, a model worthy of imitation. But Lanark has a still greater attraction in the falls of Clyde, Boniton, Corra, Stonebyres, situated above and below it, at about two miles' distance from each other. Their height does

not exceed eighty or ninety feet; but the mass of water, with the grandeur of the rocky walls and hanging woods, render them one of the finest examples of this description of scenery. The aspect of upper or mountainous Clydesdale has already been noticed; as have the lead mines also, on the extreme southern point, where it borders on Dumfries.

2057. *The northern Lowlands*, as they may be called, now claim our attention. Grand and prominent as is the natural boundary of the Friths of Forth and Clyde, it does not separate the Lowlands and Highlands. The former, beyond the Forth, form a belt of about twenty miles in breadth, which reaches to the northern promontory of Aberdeen, and thence along the shores of the Moray Frith. The coast is generally level and fertile; but a great part of the interior, though not mountainous, is bleak and moorish. This district contains, however, several cities and seaports of considerable magnitude and importance.

2058. *Fife* is a large county, which, with its appendages of Kinross and Clackmannan, fills up all the interval between the Friths of Forth and Tay. It was anciently the most flourishing part of the kingdom, being protected by the Forth from English invasion and border inroad, and secured by its distance from the *spreaghs* of the highland freebooter. Under these circumstances, Fife became distinguished as the centre of industry; and one of its cities forms the ecclesiastical capital of Scotland. All the foreign commerce of the country was carried on in its ports; and less than two centuries ago its rental amounted to a tenth part of that of the whole kingdom. Since Scotland has ceased to be agitated by war, Edinburgh and the opposite side of the Forth have attracted all these advantages; and Fife exhibits generally an aspect of decay. In particular, the numerous seaports which, at short intervals, range along the whole northern coast of the Forth, have dwindled into fishing villages. Fife is, in general, a level country, yet diversified by ranges of low eminences, and by a few hills of considerable elevation, as the Lomond Hills, and Largo Law. A great part of the interior is bleak and unproductive; the farms are small, and farming, in general, less advanced than in the Lothians; but it has still made considerable progress. In regard to manufactures, this county adheres to the old Scottish staple of the spinning and weaving of flax, carried on chiefly for domestic use, unless at Dunfermline, where there is a large fabric of fine sheeting and diaper. The western coast abounds in coal of various quality, and in very fine limestone, which is worked and exported to a very great extent. The county town is Cupar, a place of moderate size, neat, with some stir and gaiety. A much greater interest attaches to St. Andrew's from its

ST. ANDREW'S CATHEDRAL.

former greatness, from the remarkable scenes there acted, and from its splendid edifices, of which fragments still remain. It is seated on a bold coast, facing a wide bay of the German Ocean; and has two fine, broad, parallel streets, of which one is now almost deserted. The castle and cathedral (*fig. 196.*) have been completely demolished; of the first there remain only some naked walls, and of the other only a high square tower, and a gable of the chapel of St. Rule, which attests the great elegance of the entire structure. The university consists of three colleges, two of which are now united: it contains a complete school of theology and philosophy, but has no classes in law or medicine. Founded under the auspices of Buchanan, it can boast many eminent professors and pupils; though, from its almost insulated situation, it does not attract so great a concourse as Edinburgh. Of the numerous coast towns, Anstruther in the east, and Kirkcaldy in the

west, are the principal; the latter has even recovered some foreign trade, and has a considerable linen manufacture. There are two great ferries across the Forth, one at Pettycur, which it is proposed to remove to Burntisland; the other at North Queensferry, where, alone, cattle are transported across. In the interior from this ferry, is Dunfermline, now the most flourishing town in Fife. In ancient times it was a place of importance, and the frequent residence of royalty. Malcolm Canmore founded here an abbey, which became one of the richest and most spacious in the kingdom; being, if we may believe Matthew of Westminster, sufficient to contain the retinue of three courts. It was nearly demolished by the barbarous policy of Edward I., and suffered still more at the Reformation: yet its ruins evince its former splendour; and part

of them has been appropriated as the parish church. On a spot immediately contiguous, while a foundation was digging for a new church, the tomb of Bruce was lately discovered. A single wall is all that remains of this once magnificent palace. Dunfermline, no longer the gay residence of the Scottish court, is more usefully distinguished by a very extensive manufactory of damask, diaper, and other fine linen fabrics, which employ 1500 looms, and yield an estimated annual produce of 120,000*l*.

2059. *Kinross*, almost enclosed by the western boundary of Fife, is scarcely entitled to rank as a separate county. The capital, of the same name, is a pleasant little town, chiefly noted for its situation on the shores of Lochleven. This is a little lake, of considerable beauty, having, on an island in its centre, a castle (*fig. 197.*),

197

LOCHLEVEN CASTLE.

sloping down to the sea. Close to it is an ancient tower, built by Robert the Bruce, which commands a very fine view. Alloa, two miles farther down, is a busy and thriving little place, in whose vicinity are large and well-conducted mines of coal, of which about 35,000 tons are annually exported. In Clackmannanshire are also the villages of Kennet-pans and Kilbagie, which have been long the seat of very extensive distilleries.

2061. *Forfar*, more usually termed *Angus*, is on the northern side of the Tay: it is of somewhat rough aspect, the western border being encroached upon by lower branches of the Grampians, while the Sidlaw Hills, a range of considerable height, traverse the centre. Between those is a portion of the great valley of Strathmore, which is here fertile and beautiful, as is also the plain between Sidlaw and the coast. The agriculture of Angus has made considerable progress, though it is still behind that of the Lothians. Its prosperity depends chiefly upon manufactures, commerce, and fishery. The first is almost entirely employed upon flax, and chiefly in its coarser and bulkier forms; while the fishery, so far as it exceeds the object of home consumption, is chiefly of salmon, taken by stake nets, and sent, packed in ice, to the London market.

2062. *Dundee*, though not the seat of the courts, is undoubtedly the first town in Forfarshire; and, indeed, ranks fourth in Scotland as to population and wealth. It was of early importance and strength, deriving its origin from Malcolm Canmore; and it obtained a fatal celebrity through the sieges to which it was exposed; first, by Edward I., then by the Marquis of Montrose; and, last and most terrible of all, by Monk, who gave it up to indiscriminate pillage; and so great was its wealth, that his army is said to have obtained booty to the amount of 60*l*. a man. Dundee, however, has recovered from all these disasters, and is become one of the most flourishing commercial towns in Scotland. Her staple employment consists in the importation of flax and hemp, and working them into coarse linens, sailcloth, &c.

In the year ended May, 1833, Dundee imported 18,777 tons of flax, and 3380 tons of hemp, which were valued at above 700,000*l*.; and she exported 100,713 pieces of Osnaburg, 148,377 of sheeting, 33,972 of bagging, 81,754 of sailcloth, 57,242 of sacking, 69,774 of dowlas, and 13,374 of other fabrics. The entire value is estimated at about 1,500,000*l*.; four fifths of which were made in Dundee itself. There is also a considerable export of grain, almost exclusively barley, which in the same year amounted to 42,600 quarters. Dundee has belonging to her, 270 vessels of 33,000 tons; and in the above year a tonnage of 212,000 entered the port. Nine vessels, of 8177 tons, are engaged in the Greenland fishery, ten smacks in the Leith and Glasgow, and ten in the London trade; which employs also two magnificent steam vessels of 600 tons burthen each. The harbour, formerly somewhat defective, has, since 1815, been greatly enlarged by wet docks and other additions; which, in May, 1833, had cost 265,000*l*. The ferry has been remarkably improved, particularly by the use of twin steam-boats, in which loaded waggons can be ferried without unyoking the horses. Above forty spinning-mills are driven by steam, and new ones forming. A railway opens a communication into the valley of Strathmore. The population, above stated as exceeding 45,000, shows a remarkable increase since 1821, when it was only 30,500. Dundee is agreeably situated on an eminence above the Tay; the old streets are narrow and steep, but new and handsome ones are built and building in every direction; and the vicinity is adorned with elegant villas. There is an academy, distinguished by the scientific attainments of some of its teachers.

2063. *Angus* has other considerable and thriving towns. Arbroath carries on, upon a smaller scale, the same branches as Dundee; and is adorned with the ruins of a magnificent abbey. Montrose is prettily situated at the mouth of a river, bearing, in common with many others, the name of Esk. Its trade and industry are considerable; and it has a safe harbour. A number of the neighbouring gentry have been attracted by its agreeable situation, which renders it the gayest and most fashionable place in the county. Forfar, the county

198

GLAMIS CASTLE.

H h

town, but the smallest yet named, and situated in the interior valley of Strathmore, is chiefly supported by the business of the courts: there is also a manufacture of brown linens. Brechin, another inland town, lies in the midst of a rich country, adorned with fine seats; and its manufactures are considerable. Cupar Angus, so called though partly in Perthshire, is a small town, agreeably situated on the Isla, and is a great thoroughfare for travellers proceeding to and from the north. The village of Glamis is distinguished by the magnificent castle (*fig. 198.*) placed in its immediate vicinity.

2064. *Kincardine*, north of *Angus*, is a county closely hemmed in by the *Grampians* on the west: it contains, however, in its southern district, the termination of the great valley of *Strathmore*, which is here called the "How of the Mearns;" and, being sheltered by the mountains, forms a tract equally fertile and delightful. The

199

DUNNOTTAR CASTLE.

burgh. *Laurencekirk* is a neatly built village in the interior, created by Lord Gardenstone, who endowed it with a small public library. It contains a manufacture of fine snuff-boxes. *Finnan*, and other villages on the coast, are famed for haddocks, cured in a peculiar manner, many of which are exported.

northern part, on the contrary, consists chiefly of mountains and moors of the most bleak and dreary aspect. The coast is of great extent and very bold, presenting in many parts high precipitous cliffs, covered with innumerable flocks of sea birds; on one of these, formed almost into an island, the extensive remains of the castle of *Dunnottar* (fig. 199.), considered formerly as impregnable, where the regalia of the kingdom were at one time deposited, look down on the stormy waves of the North Sea. *Stonehaven*, the county town, is a cheerful seaport; and, besides being the seat of the courts, carries on some trade, and has a manufacture of brown linen. *Bervie* is only a fishing village, but with the privileges of a royal

2065. *Aberdeen* is a large and important northern county. It has a very considerable line of coast, both to the east and to the north, and extends, with increasing breadth, far into the interior. There it forms *Mar*, or *Braemar*, a highland district, one of the most elevated in the kingdom, some of the mountains rising to above 4000 feet, and containing extensive forests of ancient pines, with large flocks of wild deer, in the deep glens or valleys. From the heights of *Braemar* descend the *Dee* and the *Don*, the first of which forms some very picturesque falls in its early course; they afterwards pursue very different directions, but nearly meet at the town of *Aberdeen*. Even the Lowland districts are in general bleak and moorish, adapted only to the cultivation of inferior species of grain, and the rearing of cattle. Amid these disadvantages, the people of *Aberdeenshire* are, in general, stirring and industrious. The old staple fabric of knitting worsted stockings, which, it is said, brought once 120,000*l.* into the county, has been greatly injured by the cheapness with which these are now produced elsewhere by the aid of machinery; but in its room other woollen branches, together with those of linen and cotton, the latter to a considerable extent, have been introduced. The beautiful rock crystals called *cairnngorms*, and also the topaz and the beryl, are found in the mountains of *Braemar*; and the fine granite which abounds near *Aberdeen*, the cutting of which is considered by *Dakin* as an art peculiarly Scottish, not only affords a valuable material for domestic use, but yields 12,000 tons to be annually shipped to London and elsewhere, for pavement, bridges, and other works which require peculiar strength. The fisheries also constitute a leading occupation. That of salmon in the *Don* and *Dee*, and the whale-fishery, are extensive branches; and from the German Ocean, haddocks, cod, ling, turbot, and shell-fish, are taken in great quantities.

2066. *Aberdeen*, "the queen of the North," and the largest city beyond the *Forth*, is situated between the *Dee* and the *Don*, where these rivers fall into the sea, at about two miles' distance from each other. Old *Aberdeen* is situated near the *Don*, whose banks here are highly picturesque; but its entrance is obstructed by a natural bar, which rendered this harbour inadequate for the town, when it had entered on the career of commerce and industry. The mass of population had early settled on the banks of the *Dee*, the narrow entrance of which opens into a basin, forming an excellent harbour. It had, however, the serious disadvantage of a bar at its mouth, liable to continual increase by the sand blown from the beach which extends along the coast. To obviate this, a mole of 1200 feet in length was carried out into the sea, under the direction of *Smeaton* and *Telford*; and a channel has been formed, by which vessels of 700 tons may enter. Yet the swell of the ocean and the current of the *Dee* produced difficulties which a steam tug-boat has remedied. New *Aberdeen* is a handsome city, especially the principal street, composed of a long range of new and good houses, built of its fine granite. Its commerce, manufactures, and fishery are those of the county, all these branches centering in *Aberdeen*. This city is now the principal ship-building port in Scotland, possessing, in 1832, 355 ships of 41,671 tons burden. The old town has rather the aspect of a village, if we except the detached houses of the professors of the university, and a range of villas, the opulent tenants of which have been attracted by the agreeable situation. It is adorned by the fine old edifice of *King's College*, from which rises a square tower, with a light and elegant crown. This seminary, founded in 1494, by *Bishop Elphinston*, had for its first president *Hector Boethius*, and for some time it numbered *Dr. Reid* among its professors. The salaries are moderate, but the bursaries for poor schools are very extensive. Attached to it is a library of considerable value. *Marischal College*, founded by the *Earl Marischal*, nearly a century later, is situated in the heart of New *Aberdeen*. It is not so well endowed as *King's College*; but can boast the distinguished names of *Beattie*, *Campbell*, and *Gerard*: it has an excellent cabinet of natural philosophy, and a well-furnished observatory.

2067. *The other towns of Aberdeen* are neither very large nor very important. Peterhead is an improving place, being much frequented both for sea-bathing and for a mineral water in its vicinity; it has two natural harbours, for the improvement of which government have contributed considerable sums, in consideration of the shelter which they afford to vessels navigating these stormy seas. It sends thirteen ships to the whale fishery, and carries on that of herrings with considerable spirit. To the south is a range of precipitous cliffs, called the Bullers of Buchan, against which the waves dash with perpetual fury. Frasersburgh, near the high promontory of Kinnaird's Head, where the coast turns westward, is a small port with some linen manufacture. Huntly, in the interior, and on the borders of Banff, is a thriving and considerable place. Inverury, though the chief town in the heart of the county, is decayed and poor; but is expected to revive by means of the canal, which connects it with Aberdeen. Kincardine O'Neil is only a pleasant village, looking up toward the mountain district of Mar.

2068. *Three counties, Banff, Moray, and Nairn*, occupy that long range of coast, which, after passing, the limit of Aberdeen, continues to run westward, till it forms, ultimately, the northern shore of the Moray Frith. As in Aberdeenshire, interior districts border on the loftiest highlands; but the coast, only diversified by gentle hills, is extremely agreeable and fertile. The whole of this coast constitutes the ancient province of Moray, which the early Scottish writers describe with admiration as the most fruitful part of Scotland, and as enjoying fifteen days more of summer than any other district. Even now, the climate is extremely mild, and the soil excellent; but being far surpassed in agricultural improvement by the Lothians and other lowland tracts, this province has lost its ancient pre-eminence. Modern improvements, however, are advancing, and will, probably, soon render it equally productive with any other in Scotland. It is watered by the three large rivers, the Deveron, the Spey, and the Findhorn; the two last rising in the distant recesses of Inverness-shire. They do not bring down from these barren tracts any article of trade except timber; but they afford ample fisheries of salmon, which is exported to the computed annual value of 25,000*l*. The herring fishery also is now prosecuted with considerable success. There are no considerable manufactures.

2069. *The towns of this district are not of any great magnitude.* Elgin, the principal, which sometimes gives its name to the county of Moray, is an ancient town, not ill built, situated on the Lossie, and has, at Lossie-mouth, a tolerable little harbour; but its chief distinction rests on its cathedral, which, even in ruin, may dispute with Melrose the glory of being the finest Gothic edifice in Scotland. After having been destroyed by Alexander of Badenoch, it was rebuilt with high additional splendour, in 1414; but in 1568 the privy council ordered its leaden roof to be taken off for the payment of the army. From that time it gradually decayed; and in 1711 the great tower fell down. In a deep neighbouring valley are also the remains of the fine priory of Pluscardine. Banff is a somewhat larger and more thriving place, situated at the mouth of the Deveron; carrying on some linen manufactures, and a considerable herring fishery. Portsoy, Cullen, Fochabers, all in Banffshire, are tolerable fishing towns; the last carrying on all the trade of the Spey. The same character may be applied to Findhorn, at the mouth of the river of that name. Nairn is a neat little county town, also at the mouth of a river of its own name, possessing some industry, and frequented for sea-bathing.

SUBJECT. 2. *The Highland Counties.*

2070. *The Highlands of Scotland* form a very extensive territory, comprising somewhat more than half the surface of Scotland. They include the whole region north of the Forth and Clyde, except the belt on the eastern coast, between the friths of Forth and Moray, which has just been described. The Highlands, in their aspect, differ from the Lowlands; to a greater degree, indeed, than the Lowlands differ from England. This region consists altogether of continuous ranges of lofty mountains, which, on the borders, leave between them some of the fine and broad valleys called *straths*, but in the interior only the deep and often rocky intervals called *glens*. They are peopled by a race totally distinct from the Lowlanders. These mountaineers wear a costume, already described, quite peculiar to themselves; they speak a Celtic dialect, deep, strong, and guttural, bearing no resemblance to the Teutonic speech of the Lowlands and of England. They have ever maintained that valour, which, under Galgacus, set bounds to the career of Roman conquest, and preserved their mountains untouched by the invader; and they have since been converted from formidable foes into gallant defenders of the rest of the empire. Down to the year 1745, they acted in clans, led by hereditary chiefs, to whom they were entirely devoted, and who exercised over them a paternal but absolute sway. This spirit of clanship led them to attach themselves strongly to the hereditary right of the Stuarts, of which, under Montrose, they gave powerful proofs, which had nearly turned the tide of war in its favour. Afterwards, in 1745, they suddenly invaded England; and, in the absence of the army in Flanders, struck alarm into the dynasty of Hanover. The ultimately fatal issue of that contest broke entirely the independence of the highland chiefs. A number were either brought to the scaffold, or sent into exile; military roads were made, and forts erected in the heart of their territory; they were deprived of their heritable jurisdictions, and of all their other feudal privileges; even the national dress was prohibited, on account of the recollections it was calculated to excite. After the first alarms, however, had subsided, the British government wisely adopted the plan of conciliation, in preference to measures of severity. Pitt conceived the happy idea of forming the highlanders into national regiments, allowing even a limited use of the appropriate dress; and they have since ranked with the bravest and most distinguished troops in the British army. Out of the forfeited estates and other funds voted by government, vast sums have been expended on the Caledonian Canal, roads, bridges, and other great works for the improvement of this rude

territory. The *lairds*, deprived of their absolute power, and attracted by the gaieties and luxuries of cities, soon accustomed themselves to view their estates only as "material capitals, to be worked according to the great principles of political economy." The multitude of little spots, divided among vassals, in whose numbers they placed their strength, were thrown into large sheep-farms; and the tenants, whose ancestors had occupied the soil since the days, perhaps, of Agricola, were driven out to seek, wherever they could find it, a home, or at least a shelter. Some migrated to the lowland manufacturing cities, and a great proportion went to America; yet it is remarkable that, in consequence of the advance of commerce and fisheries, even the highland counties augmented their population during this period, though not in the same proportion as the Lowlands. Between 1801 and 1821, it increased from 434,000 to 512,000. There is one great manufacture, generally diffused throughout this region, which, unfortunately, tends rather to disturb the peace than to improve the condition of the community; this is whiskey, which the people prepare in small stills from their *bere*, or coarse barley, and give it a flavour superior to any other spirit made in England or Scotland. But, besides the inflaming quality of the article itself, the absurd fiscal regulations of the government, rendering it penal to make it on the small scale which alone suited the manufacturer, and prohibiting its admission into the low country, gave rise to a most extensive system of contraband, carried on sometimes by large bodies of men, in open defiance of the power of government. A more liberal system, however, in both these respects, has now been adopted, and has already been attended with the happiest effects.

2071. *The Highlands are composed of two great districts*, — the west and the north. The former comprehends the shires of Dumbarton, Argyle, Bute, and part of Perth; the latter embraces the counties of Inverness, Ross, Sutherland, &c. The Hebrides, or Western Isles, belong to the counties of Bute, Argyle, Ross, and Inverness. The extent of the continental district, from Dumbarton to the border of Caithness, is above 200 miles.

2072. *Perth is a noble and extensive county*, forming the link, as it were, between the Lowlands and Highlands; in its different parts uniting the utmost beauty and fertility of the one with the highest grandeur of the other. The former qualities are conspicuous in the *carse* of Gowrie; a broad sloping plain, on the north bank of the Tay, profusely covered with orchards and cultivated fields. The upper part of Strathearn, also, between Perth and Crieff, varied with gentle hills, cultivated valleys, and the windings of two great rivers, may almost be called the garden of Scotland. As we proceed to the north and west, the Grampians, appearing first as blue distant masses, gradually swell, and constitute a magnificent back-ground to every landscape. At length they are found occupying the whole interior of the county, in a line from north-east to south-west, and comprehending the mighty summits of Ben Lawers, Benmore, Bengloe, Schehallion, Ben Voirlich, Benledi, Benvenue; all from 3000 to upwards of 4000 feet high, and thus exceeding the boasted heights of Snowdon and Helvellyn. Within their recesses they enclose the three large lochs, Tay, Earn, and Katrine. As these lakes, though hemmed in by such vast mountain boundaries, do not present, generally, a desolate aspect, but are varied with woods and verdure, they exhibit in many parts scenes of almost magical grandeur and beauty. In the lowlands of Perth, agriculture is carried to great perfection; and the rents in the *carse* of Gowrie are higher than in any other merely rural district. The highland tracts, on the contrary, are in general fit only for pasturage, or, in some favoured spots, for crops of *bere*, oats, and flax. They are, however, covered with the remains of ancient forests, to which the great proprietors have been making very extensive additions. The towns of Perthshire participate in the different national manufactures: the bleachfields and print-fields are numerous; but this can in no view be generally regarded as a manufacturing county.

2073. *Perth is well built*, and, as to situation, one of the most beautiful cities in the kingdom. The view of it from the north, in particular, in the heart of a finely wooded plain, with the Tay winding round it, and the Hill of Moncrieff rising above, is almost without a rival in the kingdom. Perth has always been an important place, and, indeed, for a long time, might claim to be considered the capital of Scotland. It was the frequent residence of the kings. Parliaments and General Assemblies met there oftener than in any other place; and, in the civil contests, the possession of Perth was considered of vital importance by the contending parties. At present it has declined to a rank decidedly provincial; and its commerce, once considerable, has been almost wholly transferred to Dundee. Yet Perth is still a thriving and considerable place: it has linen and other manufactures, which produce an annual value of about 200,000*l.*; while its advantageous site, and the excellent education afforded by the grammar school and academy, attract a number of the neighbouring gentry, and render it gay and fashionable.

2074. *The other towns of Perthshire* are small, but distinguished for the grand and picturesque scenery amid which they are situated. Dunkeld, in this respect, is generally considered the pride of Scotland. It cannot boast highland scenery on its greatest scale; but the various forms of the finely wooded and rocky hills through which the Tay meanders, with the valleys and glens opening on every side, produce a diversity of landscape scarcely equalled elsewhere. The late Duke of Athol, whose spacious domains cover this part of Perthshire,

was, indeed, most active in respect to plantations, since those of Dunkeld alone are stated by Dr. Macculloch to cover 11,000 acres; and the whole number of trees planted by his grace to amount to 30,000,000. A

200

FALL OF BRUAR.

route of twenty miles, directly north, passing opposite to the fine mountain village of Logierait, and through the bold pass of Killikrankie, leads to Blair, also part of the Athol territory, and one of the most picturesque spots in Scotland. Its striking features consist in the lofty mountain Bengloe, the glens of the Tilt and the Garry, and the singularly picturesque rocky falls of the Bruar (fig. 200). Westward is Loch Rannoch, surrounded by extensive forests of fir, and overhung by Schehallion, on whose lofty summit Dr. Maskelyne performed some of his operations for the measurement of the earth. Out of it flows the Tumel, a rapid stream, which forms a small lake, and some romantic cascades. From the bridge of the Tumel, a military road leads southward to Loch Tay, the largest of the lakes, and surrounded by the loftiest mountains of Perthshire. Ben Lawers, with a chain, scarcely secondary, of attendant mountains, overhangs it from the north; while Benmore shuts it in on the west; and perhaps there is no lake in Britain enclosed by so grand a circuit. The sides of the mountains are somewhat naked; but the grounds of Taymouth, at the head of the loch, form a rich foreground.

2075. Farther south is the vale of Strathearn, at one end of which, Crieff, a thriving little town, looks up on the windings of the river, and the vast mountains from amid which it issues. Farther up is the beautiful village of Comrie, presenting some Roman antiquities, and exposed to slight shocks of earthquake. Immediately beyond this, the traveller finds himself enclosed by dark and rocky passes, leading to Loch Earn, a small lake, the waters of

which are very clear and transparent, and which is bounded on the south by grand ranges of very lofty mountains.

2076. The upper valleys of the Forth and the Teith have some very remarkable scenery, particularly the Forth, which, above Stirling, is the more considerable stream. On its tributary, the Allan, is Dumblane; a pleasantly situated little town, with the remains of a fine cathedral; and now rendered an object of considerable resort by a mineral spring recently discovered at Airthrie in its vicinity. Up the river is Doune, with a cotton manufacture, and the remains of a castle. Callender may be considered a highland village, being overhung by Benledi, along whose side the pass of Lenie leads into the interior highlands: it is chiefly frequented as the key of Loch Katrine, situated about ten miles to the westward, and approached by a narrow road along the small lakes of Venachoir and Achray. The scenes of fairy beauty and grandeur which adorn the eastern extremity of this lake, the mighty cliffs of Benvenue, the wild wooded glen of the Trosachs, and the beautiful little island in the centre of the scene, are now familiar to the eyes of Scotsmen, celebrated as they have been in the verse of their favourite bard. Farther south, the Forth, rising from Ben Lomond, rolls through a pastoral mountain valley, once the seat of the power and the scene of the adventures of the outlaw Macgregor. It forms several little lakes, of which Loch Ard is the largest and most beautiful. On joining the Teith, near Stirling, the Forth, though every way inferior, has the fortune to give its name to the united stream. It may be proper to notice, that Perthshire shoots a narrow stripe between Fife and Clackmannan down to the Forth, on which stands Culross, properly a Fife town, near which are considerable mines of coal, not found in any other part of Perthshire.

2077. The county of Inverness, to the north of Perth, fills a vast mass of the central highlands, reaching at one point from sea to sea. It nowhere borders on any of the lower parts of the kingdom, but is purely and completely highland, presenting range after range of mountains, of which Ben Nevis, Cairngorm, and several others, are the most elevated in the United Kingdom. The intervals between them are filled either by long lakes, or by narrow glens, the level space of which does not usually exceed a mile in breadth. The principal one, that called the Great Caledonian Glen, reaches from Inverness in an oblique direction across the kingdom, filled with an almost unbroken chain of lakes,—Loch Ness, Loch Oich, Loch Lochy, and Loch Linnhe; which last opens by the Sound of Mull into the western sea; a continuity which suggested and facilitated the formation of the grand navigable line of the Caledonian Canal. The tracts reaching westward to the sea are, if possible, still more vast and desolate; glens, which run generally from east to west, are often filled by these long arms of the sea called in Scotland *lochs*. In the east, the most remarkable district is that along the upper course of the Spey, bearing the name of Strathspey, and comprising an unusual extent of level land. In general only about a fortieth part of the county is understood to be capable of cultivation; but that fortieth, composed of *haugh* or alluvial land, on the banks of the rivers, or at the head of the lakes, is extremely fertile. By far the greatest branch of industry consists in the rearing of black cattle, sheep, and goats. Game of all kinds, including deer, abounds so much as to render the county a desirable resort for the adventurous sportsman; and many of this class, even from England, take up their summer residence in its mountain recesses. There are still considerable remains of the great Caledonian forest, composed chiefly of fir; but the greater part is fallen, and its traces are found in the mosses which cover a great part of the county. Unlike most mountain tracts, this district does not yield minerals of any value; and there is little to be said as to manufactures, if we except whiskey, for which some districts are famous.

2078. Inverness, the gay capital of the Highlands, is of a very different character from that of the wild region over which it holds a sort of dominion. Seated on a bay, at the head of the Moray Frith, it partakes in a great measure of the mild and fertile character of its shores, and stands at some little distance from the awful ranges of mountains by which it is enclosed. After suffering a considerable decline from its ancient importance, it has, within the last

thirty years, nearly tripled its extent and population. This is owing to the great resort of the neighbouring gentry, who are more than a hundred miles distant from any other city; to the many tourists, who make this the centre of their excursions; and to excellent institutions for education, which cannot elsewhere be found in the Highlands. In general, a considerable polish of manners is observable; and it has been remarked that the English language is spoken in greater purity than in any other part of Scotland; a circumstance which has been ascribed to the residence of English officers after the battle of Culloden. Inverness has a town house, infirmary, assembly-rooms, theatre,—all the appendages of a lowland city. Manufactures of hemp, flax, and tartan have been established. The views, both of sea and land, in its vicinity, are almost unrivalled.

2079. *Inverness-shire has scarcely another place which can make much pretension to the name even of a village.* The most prominent objects consist in the chain of forts which, after the alarm of 1745, were erected with the

FALL OF FYERS.

view of holding the Highlands in check. Fort George, east of Inverness, on a peninsula at the end of the Moray Frith, is of great strength, and regularly constructed. Fort Augustus and Fort William are situated on the chain of lakes, the one at the opposite end of Loch Ness, and the other on Loch Lochy. The garrisons have now been withdrawn, and arrangements had been made entirely to dismantle the forts; but this last measure has been stopped. The villages formed around these forts still supply with imported goods a vast extent of ill-inhabited country. Near Fort William rises Ben Nevis, usually considered the loftiest mountain in Scotland and in the United Kingdom, being 4370 feet above the level of the sea. This mountain, however, though steep and so lofty, is not picturesque in its form; its summit is a naked plain strewn with rocks; but the view is very extensive, embracing a great portion of the Hebrides. To the east of Loch Ness, the rivulet of Fyers or Foyers (*fig. 201.*), forms the greatest waterfall in Scotland; the lower or principal fall descends from a height of 212 feet. The stream is not very copious; but the accompaniment of rocks, either precipitous, or covered with birches, plants, and shrubs, renders the scene highly picturesque. The western coast, opposite to Skye, is indented with several large

inlets or lochs, on which villages have been built, and the herring fishery is prosecuted with considerable spirit.

2080. *Argyle, the next division,* is very commonly called the Western Highlands. It is a wide and irregular territory, stretching into long promontories, and indented by deep arms of the sea, so as to form a coast of very great extent. In general, however, the shore is bordered by high hills and steeps, and the interior covered with ranges of rugged and awful mountains, similar to those of Inverness and the interior of Perth. Its industry, therefore, is almost entirely pastoral; herds of black cattle and vast flocks of sheep are fed on the sides of its mountains. The manufactures are trifling; and if Argyle possesses mines, they have not been worked with any vigour or success. But this county has actively improved the opportunities of fishery, which the wide range of its coasts affords. The herring of the west coast, and especially of Loch Fyne, enjoys a higher reputation than any other variety of that numerous and valuable species. It has been supposed that the spirit of clanship is felt in this county with greater ardour than in any other part even of the Scottish highlands. The county is chiefly tenanted by Campbells, who were wont to rally round the Maccallummore, a designation of their chief the duke of Argyle, with all the ardour of kindred and national attachment; and several of the house of Argyle have exercised a peculiarly powerful and auspicious influence on the fortunes of Scotland.

2081. *Dumbarton forms a county which must be mentioned before we enter into the*

DUMBARTON CASTLE.

details of Argyle. The greater part of it is properly a part of the same district; yet it has a lowland stripe extending along the northern banks of the Clyde. The western part, though somewhat bleak, is marked by two grand features: the Great Canal, joining the Clyde at the village of Dunglass; and the almost parallel line of the wall of Antoninus, called by the Scottish vulgar "Graham's dike." The approach to Dumbarton affords one of the most striking prospects in Scotland; the broad bosom of the Clyde covered with numerous vessels, and its castle (*fig. 202.*), the ancient and mighty hold of the Britons, towering on the summit of a perpendicular rock, and still maintaining

its importance as a fortress. Dumbarton has a large manufactory of crown glass, which

is exported to all quarters of the kingdom, as well as to foreign parts; and on the banks of the Leven there are extensive printfields. Here terminates the lowland of Dumbarton, and the rest forms naturally a part of Argyle, or the Western Highlands.

2082. *Loch Lomond* (*fig. 203.*), the first great feature, both by its extent and beauty,

LOCH LOMOND.

Luss they are remarkably united. The numerous and beautiful islands, and the long wooded promontories stretching into the water, with the majestic form of Ben Lomond in the back ground, produce a combination of landscape which perhaps no other spot in Britain can equal. Luss is a mere village; and there is no other place on Loch Lomond which can deserve even that name, though there are inns at convenient distances.

2083. *On turning the head of Loch Long at Arrochar*, a fine retired and tranquil scene, the view opens on the romantic valley of Glencroe. On entering it, the traveller is enclosed between two ranges of mountains rising almost perpendicularly to an amazing height, and leaving between them only a narrow vale, through which a rivulet flows. The greatness of all the surrounding objects fills the traveller with sublime emotions, sometimes even mingled with terror; especially when, arrived at the hill which bounds this extraordinary vale, he looks back and sees all its enormous features concentrated round him. The vale of Glenfinglas is then passed, whose high sloping sides covered with innumerable flocks inspire pleasing pastoral images, and at the termination of which appears the grand estuary of Loch Fyne.

2084. *Inverary*, the capital of the Western Highlands, is situated near the head of Loch

INVERARY CASTLE.

Fyne. Its environs are not mountainous; but its noble castle (*fig. 204.*), surrounded by wooded hills and wide lawns, the open extent of its prospects, with the lofty mountains which shut in the distant view, render it a magnificent and delightful spot. The other lakes inspire ideas of peace, retirement, and seclusion; this delights by the display of almost regal pomp. The town itself is small and neat, without any employment, except that arising from the herring fishery,

and the visits of numerous strangers, who are now conveyed by the steam packets in ten or twelve hours from Glasgow. About ten miles below Inverary, the Crinan Canal joins Loch Fyne to the western sea, and has made Lochgilphead a place of some consequence. Farther down is West Tarbet, a pleasing little town, situated on a rocky isthmus in the route to Islay.

2085. *The interior and the western coast of Argyleshire* are in many respects interesting. Parallel to Loch Fyne, at the distance of ten or twelve miles, is the long line of Loch Awe; an interior lake, over whose head towers Ben Cruachan, the loftiest summit in Argyle. The castle of Kilchurn, rising on one of the islands, produces a highly picturesque effect. Beyond this, Loch Etive, a narrow arm of the sea, stretches far into the interior. Its head is enclosed by ranges of high and steep mountains, and its lower part displays the phenomenon of a fall, or at least succession of rapids, down which the whole lake throws itself with prodigious noise and a long train of white billows. This fall appears only at low water, when it is six feet high, but is covered over by the sea on the rising of the tide. At a corner of this lake is Bunawe, where a Lancashire company some years ago established an iron foundry, now nearly abandoned. Climbing the high mountains at the head of Loch Etive, we come to an awful recess, Glencoe, which in terrific grandeur surpasses perhaps every other spot in Great Britain. This effect is produced by its bold and broken mountain forms, its spiry rocks, and black precipices; at the bottom of which, in a deep chasm or ravine, flows the rivulet of Coe. This stream is the Cona of Ossian, believed the favourite haunt of that celebrated Caledonian bard. The vale has also a gloomy recollection attached to it, from the massacre of 1691, which was inspired by private vengeance, but to which the sanction of William III. was surreptitiously obtained; but the enquiry into this transaction never satisfied the nation. Emerging from this gloomy scene, the traveller is cheered with the gay aspect of Loch Leven, which presents much pleasing highland scenery, while the hills round the ferry of Balachulish afford valuable quarries of slate.

2086. *The extensive and varied western coast of Argyleshire* next demands notice. From Balachulish, along

the broad expanse of the Linnhe Loch with which the great Caledonian chain terminates, extends Appin, a beautiful district, diversified with fine woods, rich pasturage, and more culture than is usual in Argyleshire. On the opposite side of the Linnhe Loch is a wide, triangular, and peninsular district called Ardnamurchan; separated only by a narrow sound from the Island of Mull. It presents the usual highland scenery, without any thing bold or peculiar; but the central district of Strontian, besides the earth bearing its name, contains lead mines of some value. Crossing the Linnhe, and passing Lismore, a long, level, and fertile island, we find Lorne, separated by Loch Creran from Appin, to which it is even superior in beauty and fertility. Near the opening of Loch Etive into the sea, tradition places Beregonium, the reported capital of the Picts in the third century; and near it is found Dunstaffnage (*fig. 205.*), once the scene of Scottish regal pomp, now a ruin,

205

DUNSTAFFNAGE CASTLE.

name of Macdonald is still common in the district, though that of Campbell predominates. The hills are not near so lofty as in central Argyle, and there is a greater proportion of level land. Campbelltown, near its southern extremity, is a thriving port, now the largest on this coast, and serving in particular as a general rendezvous for the herring fishery.

2087. *The three extreme counties, Ross, Cromarty, and Sutherland, form the most remote and northerly portion of the Highlands, and, Caithness excepted, of all the mainland. The south-eastern border of the friths of Moray, Cromarty, and Dornoch contains some fine land, and several thriving towns; the rest is a continued range of rock, mountain, heath, forest, and loch, similar to Inverness, but still wilder. The lochs which indent the western coast are large and numerous, particularly Loch Carron, Loch Terridon, and Loch Broom; and they have generally grand mountain boundaries. On these the neighbouring proprietors, or the Board for the Encouragement of the Fisheries, have erected villages, with the view of employing in the herring fishery the natives ejected in consequence of the modern system of sheep-farming; and the success has been very considerable. The principal of these stations is Ullapool on Loch Broom, a considerable village, with an excellent and spacious harbour. The most picturesque of the western lakes is Loch Maree, which is almost enclosed by land, with a fine circuit of mountain, and in the number of its wooded islands resembles Loch Lomond. Cape Wrath, the north-eastern point of Scotland, is a lofty pyramidal rock,*

206

DUN DORNADILLA.

standing in front of a vast range of broken cliffs, and breasting the whole wide expanse of the ocean. On the northern coast in Loch Eribol, a wide inlet, bordered by limestone rocks, perforated by caves of great extent and remarkable form. Sutherland presents numerous *Duns*, or ancient forts of peculiar structure, of which the most remarkable is Dun Dornadilla (*fig. 208.*), situated on the lofty sides of Ben Hope, not far from Loch Eribol.

2088. *Of the small towns in this northern region, Cromarty, the capital of the little county of the same name, stands at the foot of its own frith; while Dingwall, the county town of Ross, is situated at the head. This frith forms a noble and secure bay, which would be of the greatest value in a commercial part of the kingdom. Cromarty is now a very considerable fishing station; and Dingwall has done a good deal to improve its own harbour. On the south side of the Dornoch Frith is Tain, where a good academy has lately been established; and on the north is Dornoch, an ancient town, once the seat of the Bishop of Caithness, of whose cathedral some part still remains.*

2089. *Caithness forms the north-eastern angle of Scotland, connecting it with the northern islands. Though enclosed by the Highlands, it is scarcely a highland county, being traversed indeed by ranges of low hills; but only the Paps of Caithness, as they are called, rise to the character of mountains. Its surface is moist, bleak, and bare, filled with little lakes, and covered with extensive moors. There are, however, about 50,000 acres of arable land, on which are raised oats and bere sufficient for internal consumption. The chief branch of industry is now the herring fishery, upon an immense scale, and on the very ground formerly monopolised by the Dutch. Kelp to a considerable extent is also made from the sea-weed thrown on its shores. Thurso, the county town, is a handsome and improving place, in the midst of a cultivated country. Its bay affords a safe roadstead, peculiarly valuable for ships, which, in rounding the north of Scotland, must pass through the Pentland Frith, rendered dangerous by its violent and rapid currents. Wick, the grand rendezvous of*

the herring fishery, attracts vessels even from remote parts of Scotland, and owes to this advantage a very rapid increase. The north-eastern point of Caithness and of Scotland bears the familiar appellation of John O'Groat's house; though Dr. Macculloch assures us that there is not even the vestige of a house to correspond to this title, which is founded on a mere traditionary story.

SUBSECT. 3. *Scottish Islands.*

2090. *The islands appendant on Scotland* form one of its most extensive and conspicuous features. Though neither rich nor fertile in proportion to their extent, they exhibit a great variety of bold and striking scenery, and are peopled by a race whose habits of life and forms of society are peculiar to themselves, and more inartificial than those of perhaps any other people of Europe. They may be divided into the islands at the mouth of the Clyde, the Hebrides, or Western Islands, and the Northern Islands, or those of Orkney and Shetland.

2091. *The islands of the Clyde are chiefly Bute and Arran*, with the smaller ones of the Cumbrays and Ailsa. Bute is of beautiful aspect, green, rocky, and hilly, with a climate accounted the mildest in Scotland, and for that reason resorted to by consumptive and other invalids. It has not within itself any alpine features, yet has in full view the high ranges of Argyleshire and the spiry summits of Arran. Extensive plantations have been formed by the Marquess of Bute; and a considerable part of the surface is arable and well cultivated. Rothsay is a gay pretty town, on the route of all the steam-packets which proceed to the Western Isles, much frequented for sea-bathing, and enriched by a considerable herring fishery. Arran presents much bold alpine scenery, the central mountain of Goatfield rising to nearly the height of 3000 feet, while the glen of Sunox at its base has the highest character of savage and romantic grandeur. The agriculture of Arran, which labours under many obstacles, and was long in a backward state, has lately been much improved. Lamlash, the principal town, possesses an excellent harbour, formed chiefly by the island opposite to it, in which there was once a large monastery, and which is valuable from the safe refuge it affords to the shipping of the Clyde.

2092. *Of smaller islands* may be noticed, almost immediately at the mouth of the frith, the two Cumbrays, the larger of which presents to the sea a sloping and fertile surface; the smaller is rocky, containing only a lighthouse. Ailsa, off the Ayrshire coast, is a rock 1000 feet high; and its lofty basaltic cliffs, formed into columns several hundred feet in height, and covered with clouds of sea fowl, render it a striking and remarkable object.

2093. *The Hebrides, or Western Islands*, are a much more extensive and varied group. From nearly the southern point of Argyle, they extend along the western coast of Scotland, and stretch pretty far into the Atlantic. Their general aspect is highland in the extreme, with rude rocks and mountains, deep and dark valleys, large expanses of peat moss, hill pastures, and scanty harvests; yet they have some peculiarities. The mountains ascend rather in single peaks than in long ranges; and the rocky cliffs which face the sea assume, in many places, columnar forms of peculiar grandeur. There are none of the extended lochs peculiar to the Highlands; but the little lakes, or large ponds, are almost innumerable. Considerable tracts of sandy soil occur, in some parts tolerably fertile, though liable to be blown by the winds; and several tracts are covered with a profusion of beautiful flowers. The climate is extremely moist; yet it is milder, and the seasons are somewhat earlier, than on the mainland. These islands have passed through several vicissitudes. The earliest possessors seem to have been Celtic. About the eleventh century, they were conquered, along with Orkney, Shetland, and Man, by Harold Harfager, and were governed for several centuries by a Norwegian dynasty, which appears to have included able and enlightened princes. Their power, however, was broken by the battle of Largs; soon after which the Hebrides owned the nominal sovereignty of the Scottish kings, but fell really under the sway of the Macdonalds, lords of the Isles, partly of Norwegian descent. Their territory, including a great part of the west coast of Scotland, formed a considerable power, till the severe check sustained at the battle of Harlaw; after which it fell partly under the dominion of the Scottish crown, and was partly divided among a number of petty chiefs, whose feuds and conflicts deform the subsequent pages of Hebridean history. At present these islands may be considered as retaining more of the spirit of clanship, and of the genuine original highland habits and feelings, than any part of the mainland.

2094. *The Hebrides may be divided into two main ranges*. One of them consists of the large islands of Islay, Jura, Mull, and Skye, with several minor attendants, which are nearly contiguous to the west coast, and separated from it only by narrow straits and sounds; the other is composed of North and South Uist, Harris, Lewis, which are considerably out at sea, and are classed, with no very strict propriety, under the general appellation of Long Island.

2095. *Islay* has an aspect somewhat different from that of the other Hebrides: it contains a good deal of level and fertile territory, with mountains neither very lofty nor very rugged. These advantages, though attended with a diminution of picturesque effect, were sufficient to induce the lords of the Isles to make Islay their residence; so that "the kings that in Islay kept state" are enumerated as at the head of the insular potentates. More recently an active spirit of improvement has visited Islay. Opulent tenants have introduced improved modes of cultivation; good crops of barley, oats, and even wheat, are raised; and the black cattle,

which form the main export, are held in great estimation. It has even a manufacture of linens, which are exported to the value of about 5000*l.* and contains lead mines, though of no great value. The ruined churches are pretty numerous; but upon the whole there are no remains to attest the seat of any splendid monarchy. Bowmore is a large village, or even small town, at the extremity of the largest loch, Daal, well frequented by shipping.

2096. *Jura* is separated from Islay only by a sound, the opposite sides of which correspond so exactly as to suggest the idea of their having been disjoined by some violent shock. The island itself, extending twenty-six miles along the parallel coast of Knapdale, is bleak and bare, even beyond most of the Highlands; it is "one continued tract of brown and rocky mountain pasture." Its mountains form a long continuous ridge, which rises at the southern point into three detached and conical summits, called Paps: these make an imposing appearance from a distance; but in the interior no striking object occurs, though the view from the summit is very extensive. The western coast consists of rugged rocks traversed by torrents, and often broken into caves, but has scarcely any inhabitants. The eastern shore, as it slopes down from the mountains, has some level and inhabited tracts; though all the inhabitants, if collected, would scarcely people a large village. In a line with *Jura*, for several miles, extends *Scarba*, consisting of a single conical mountain broken into rocky precipices, and forming on the eastern side a very striking and romantic object. Between *Jura* and *Scarba* is the perilous strait of Corryvreckan, a whirlpool noted for shipwreck. *Colonsay* and *Oronsay*, considerably to the north-west of *Jura*, form one long small island, the channel between them being passable at low water. The former, in the interior at least, has rather a peculiarly verdant and smiling appearance; while at *Oronsay* are seen the remains of a priory, ranking as the finest in the Highlands next to that of *Iona*.

2097. *Mull* is a large, round, rough, stormy island, with winding and deeply indented shores, separated by a long narrow sound from the rudest part of the Argyshire coast. The interior is a confused troubled heap of mountains, destitute, in general, of any thing striking or picturesque. The shores are almost every where rocky and precipitous, presenting, especially on the western coast, interesting varieties, rocky labyrinths, deep recesses, and ravines clothed with shrubs. The two once mighty holds of *Duart* and *Aros* crown rocky cliffs on different points of its eastern shore. The great keep of the former, with its walls nine feet thick, encloses an area of thirty-six feet by twelve. The industry of the people of *Mull* consists chiefly in rearing a small breed of black cattle, and black-faced sheep, celebrated for their delicate mutton. Of the former about 1300, and of the latter 4500, are exported; also 600 tons of kelp, and a considerable quantity of herrings. The Board of Trustees for Scottish fisheries have built at *Tobermory* rather a handsome and rapidly increasing little town. But *Mull* is chiefly remarkable for its small insular appendages on the west, *Staffa* and *Iona*.

2098. *Staffa* is a small island, or rather large rock, about a mile and a half round, and encircled by cliffs, which, according to Dr. Macculloch, nowhere exceed in height 144 feet, but contain a wonder of nature, to which she has scarcely produced elsewhere a parallel. This is the Cave of Fingal (*fig. 207.*), as it is called, which remained unobserved, amid

207

FINGAL'S CAVE.

its rocky barriers and stormy seas, till 1772, when Mr. Leash, an Irish gentleman, on a fishing excursion, discovered this cave, and gave notice of it to Sir Joseph Banks, who visited *Staffa*, and made it known to the world. Almost all the rocks of the island are basaltic and columnar; but here they are arranged so as to produce the most singular and magnificent effect. An opening, sixty-six feet high and forty-two wide, formed by perpendicular walls terminated by an arch at the top, admits into a natural hall, more than two hundred feet long, and bounded on

each side by basaltic columns rising in regular symmetrical succession. The above dimensions are those given by Dr. Macculloch, and considerably lower than the result of the original measurement by Sir Joseph Banks. Two other caves, the Cormorants' Cave and the Boats' Cave, present similar scenes, but with interesting varieties. Of the columnar rocks, which extend over a great part of the island, many are bent and twisted in a remarkable and very beautiful manner.

2099. *Iona* (*fig. 208.*) is a small island near *Staffa*, of greater extent, with some cul-

203

IONA.

ture, and a scanty population, but no natural features that deserve notice. Yet it excites the deepest interest by the venerable ruins which attest, in this secluded corner, the early existence of religion and learning, at a time when the rest of the kingdom was buried in barbarism. Amid all the uncertainty of our early history, it appears certain that St. Columba, about the middle of the sixth century, founded here a monastery, and made it a centre whence he endeavoured to diffuse the

light of Christianity. This religious establishment was enriched and extended, and a nunnery was afterwards instituted under the same auspices. The Culdees, or followers of Columba, appear to have rendered very great services to Britain, and even to the whole North. Teachers were often drawn from among them for seminaries in England; and they undertook missionary expeditions to Norway, and even to Russia. They taught, in a great measure, the pure principles of primitive Christianity, rejecting both vows of celibacy, and the pompous ceremonies of the Romish church. By degrees, however, a system expressly formed to dazzle and allure the multitude prevailed over one suited to a pure and primitive people; and Iona itself at length became Roman catholic. It continued, however, to flourish till the Reformation, when its monks were dispersed, and its edifices demolished. The library of Iona was formerly famous, though probably its collection of classic authors, brought by Fergus II. from the sack of Rome, may be ranked as a fable. The cemetery also remains, in which, according to tradition, were buried forty-eight kings of Scotland, eight of Norway, four of Ireland, and one of France. Allowing the scepticism of Dr. Macculloch as to this magnificent list, it appears confirmed, from the ornaments on the tombs, that many of the West-Insular chiefs chose this as a sacred spot, where their ashes might repose. The ruins are extensive. The cathedral is 164 feet long and 34 broad; and near it is a chapel sixty feet long. The style of architecture is early and rude; and the sculptures, though pretty numerous, are, with a few exceptions, grotesque in design and execution. The finest part consists of four crosses, the remnant of the probably much exaggerated number of 360, once belonging to the edifice. The altar, of pure white marble, has entirely disappeared.

2100. *Other small islands occur in the vicinity of Mull.* Ulva and Gometra are rocky and barren, though the former especially has basaltic cliffs; while on the outer border, the Freshinish islets are of the same character, and only remarkable for the rocky site of the ruined castle of Cairnburry. About twenty miles westward of Mull are the two long narrow stripes of Coll and Tiree, separated from each other by one of the usual narrow sounds. Tiree presents a very striking contrast to the other isles, being so low and flat, that it appears as if the waves would sweep across it. The soil is sandy, but in general very fertile in the highland grains, oats and bear: it carries on a considerable fishery; and has veins of fine marble. Coll presents a quite different aspect, being composed of rocky hills, with broad flat tops; so that from a height it appears a mere unvaried plain of rock. Between these hills, however, are green dells; and though it is said that there never was in Coll a plant more than three feet high, yet both it and Tiree yield a profusion of beautiful flowers.

2101. *Skye, the most northerly of this inner chain, may be ranked also as the largest and most considerable of the whole group.* It is forty-five miles long; but its shores are so winding, and so penetrated by lochs, that it may be said to form a cluster of peninsulas. Ranges of rocky mountains, many of them 3000 feet high, cover almost the entire surface. On a first approach, its aspect is only bare, bleak, brown, and dreary; but in sailing round its shores, the high rocks with which they are every where bordered occasionally display objects of striking and romantic grandeur. The north-east shore exhibits an almost continuous range of perpendicular cliffs, about 500 feet high, with only occasional openings. Inland, above this, rises the Storr, consisting of rows of basaltic columns, in many places taller than those of Staffa, though they nowhere form the same regular and majestic dome. Still more marked are the Cuchullin Hills, on the south-eastern coast, which present crowds of rugged and broken summits, more resembling the Alps than those of any other part of Britain. Within their recesses, Dr. Macculloch traced Loch Scavig and Glen Coruisk, which last he considers as superior in gloomy grandeur even to Glencoe. In Strathaird, approaching to the southern point, is the celebrated spar cave; it is about 250 feet from the entrance to the extremity; but a great part of the passage is gloomy and rocky, and only in its most interior part do the stalactites begin to branch out into that variety of intricate and brilliant ornaments which make the cave so beautiful. The great body of the island is described as a hilly moorland, barren, brown, and rugged; the peaks being generally from 500 to 1000 feet high. The eastern coast of Sleat or Slate, the most southern peninsula, and in the north, the shores of Loch Bracadale and Loch Snizort, and the plain of Kilmuir, are level and arable. Almost the sole occupation is the rearing of cattle, which are of good quality, and the exportation of which, with that of a considerable quantity of kelp, forms the chief trade of the island; large quantities of herrings are also taken, and cured by fishermen who carry on this branch of commerce on a small scale. The only places which can be called towns are Broadford and Portree, on the eastern coast, which maintain the communication with the continent. The property of Skye is almost shared between the family of Lord Macdonald, who claims descent from the ancient lords of the Isles, and that of Macleod. Duntulm, the almost ruined seat of the Macdonalds, retains many peculiarities of the ancient feudal castle, among which the pit and gallows are not wanting. The Macleods' castle of Dunvegan, founded in the thirteenth century, is also a magnificent pile: both are on the north-west coast of the island.

2102. *Skye has many attendant islets.* On the east is Rasay, masked by long lofty cliffs of fine sandstone, out of which cities might be built, and which have on their tops green and cultivated farms. It is separated by sounds on the north, from the barren and solitary isle of Rona, and on the south from Scalpa, a long island consisting of a single mountain; and the sound between which and Skye is covered with vessels passing to and from the continent, or engaged in the fishery. To the south-west is Rum, a wild and rugged mass of mountains, surrounded by shores scarcely accessible, and involved in almost perpetual tempest. The mountains, however, being lofty, and in general but partially visible through clouds, render Rum a magnificent object when seen from the sea. On the west is Canna, a small island surrounded by ridges of columnar rocks, rising in successive stages, but with rich verdant vales on their tops. On the east of Rum is Egg or Eigg, also surrounded with bold cliffs, particularly the Scur, which extends about a mile in length, presenting a perpendicular face of nearly 500 feet, with a flat summit. Eigg contains also several large and remarkable caves: this isle, with Skye and its appendages, terminates the interior chain of the Hebrides.

2103. *Long Island* is the general name given to the exterior chain of the Hebrides, with no strict propriety, since the tract consists of five large, and many smaller islands; but these, forming a line of nearly 150 miles, are so closely contiguous, separated only by narrow sounds filled with islets, that the whole may, without any extreme licence, be considered as one island. Though as rude as the eastern range, it is not so generally mountainous; it is a strange mixture of bogs, rocks, lochs, and sands. Owing to the difficulty of conveying sheep by sea, its pastures are chiefly occupied with cattle destined for the markets of the mainland; and from the abundance of sea-weed on its winding and extensive shores, large quantities of kelp are produced, which yield considerable profit.

2104. *Lewis* is the largest of all the Hebrides, being upwards of eighty miles from north-west to south-east, and at some points more than twenty in breadth. It is not, however, favoured by nature, but presents the general bleak aspect of the western Hebrides, with only a green belt along the coast. Of its inhabitants, those occupying its most northern point, called the Butt of Lewis, appear to be Danish; the remnant of that colony who once ruled the island. The people are industrious in cultivating their rude soil, and in the fisheries, which have rendered Stornoway, the capital of Lewis, a place of some consideration, even in this remote region. It

was made a borough by James VI., and its present prosperity is marked by the foundation of a new town, of lowland aspect.

2105. *Lewis has some small but striking appendages.* To the east are the Shiant Islands, the largest of which, Gariveilan, presents to the sea a range of columnar cliffs more than half a mile long, and varying in height from 300 to 400 feet, one of the most magnificent colonnades to be found in the Western Isles. To the west are the Flannan Islands, seven in number, with some rich verdure, but chiefly remarkable for the swarms of sea-fowl which fill the air with multitudinous clamour. About sixteen miles to the north is Rona, supposed the extreme north-west point of Britain. It is about a mile long, and, in high seas, the spray of the Atlantic sweeps entirely over it. Yet it has green and fertile land, occupied and cultivated by a single tenant.

2106. *Harris, a peninsula on the southern point of Lewis, and almost ranked as a separate island, is of very different aspect, consisting of a mass of rugged rocks, which project in long promontories into the sea, giving to the shore a very picturesque aspect.* The arable patches are small, and in such inaccessible sites that they cannot in general be reached without great labour, and can be cultivated only by the spade. Sheep are more numerous than black cattle, being better adapted to this rugged surface.

2107. *North and South Uist, with Benbecula, exhibit the general aspect of Long Island, of whose length they compose about eighty miles.* The western shore, for a mile or two in breadth, is flat and sandy, producing in summer tolerable crops of oats and bear, but wearing in winter a most dreary aspect: in the middle, bogs, peat-mosses, lakes, and ponds, without number; on the east, a rude and rocky coast penetrated by deep sea-lochs. The cattle are small, and not exported in very large quantities. The most flourishing branch of industry is kelp, for which the shores of these islands afford ample materials. The two Uists are said to yield annually about 2500 tons, for the fabrication of which about 60,000 tons of sea-weed would be requisite. Benbecula, intermediate between the two Uists, is of a similar character, but more dreary than either; a mere waste of waters, rocks, and sand.

2108. *Barra, the most southern branch of Long Island, is small, but distinguished for the industry of its fishermen, who, in large boats, carry their cargoes through the Crinan Canal to the Greenock market.* About half a mile from the northern shore is Chisamil, the castle of the Macleans, now partly in ruin, but of such extent as to have been capable of containing 500 men. From Barra, southwards, stretches a chain of islets terminating with Bernera, commonly called Barra Head.

2109. *We must not leave the Hebrides without commemorating St. Kilda, its remotest point, small and solitary, far out in the Atlantic, whose waves dash continually against its perpendicular cliffs.* It is about three miles long, girt on all sides by a wall of rock, which at one point is about 1300 feet high; Conoxhan, the loftiest hill on the island, being there cut down perpendicularly from the summit to the base. "Dizzy heights, from which the eye looks down over jutting crags; a boiling sea below, without a boundary; dark cliffs beaten by a foaming surge, and lost in the gloom of involving clouds; the mixed contest of rocks, ocean, and sky," are the scenes which characterise St. Kilda. On the top of the rocks is a green and somewhat fertile surface, on which are fed sheep of the Norwegian breed, with short tails and coarse wool, but

whose mutton is delicious; there are a few cows; and a little very fine bear is grown. But the favourite food of the natives is drawn from the face of the perpendicular cliffs which, in fearful and dizzy height, overhang their shores. Suspended by a rope, they step from point to point, and take the eggs or young of the solan goose, puffin, cormorant, petrel, and others of the numerous species which breed on their sides. The population, which Martin calculated at 180, is reduced, according to Dr. Macculloch, to 110. Poetical description has ascribed to them the simplicity of the golden age; and they really appear to be harmless, quiet, and laborious; though by repeated intercourse their manners are now much assimilated to those of the other Hebrideans. They laboured formerly under great want of instruction; and scarcely any could either read or speak the English language; but of late, through the exertions of some Lowland societies, a missionary has been sent and a school established there.

2110. *Only the extreme insular ranges remain now to be described; which stretch from the northern boundary of Scotland towards the Polar Sea. These are the Orkney and Shetland Islands.*

2111. *The Orkneys form a group of about thirty in number; but Pomona or Mainland contains nearly as much ground as all the rest put together.* Nothing can be more irregular than their form; the deep sounds by which they are penetrated, and the narrow straits which separate them from each other, cause a complete intermixture

of land and sea. These straits are rendered dangerous by numerous currents and eddies from the two oceans which rush in from opposite sides. The Pentland Frith, in particular, between Orkney and the Mainland, is a most formidable passage. The opposing

currents keep the channel in a state of perpetual ebullition, and produce, at several points, violent whirlpools; among which the Wells of Swinna, the Seralchie of Stroma, and the Merry-men of Mey, are named with particular dread. Orkney has not an inviting aspect. It is in general low, bleak, boggy, and bare; though its western islands face the Atlantic with some very bold and rugged cliffs. About a twelfth part is cultivated in a rude manner with the plough; a somewhat larger portion is under regular pasture; the rest is moor and waste. The cattle, though small, are of a good breed, and about 50,000 sheep, almost in a wild state, roam through the commons. The fisheries are not extensive, but sea-fowl, as well as moor-game, are pursued with activity. Kelp is the staple commodity for export: it has averaged annually 2500 tons, employing 3000 men. There is some coarse woollen, and of late there has been some linen manufacture. As most of the vessels destined for Hudson's Bay and the whale fishery, and many of those which, from the east coast, sail to all parts of the world, pass by the north of Scotland, the ports of the Orkneys are frequented, and a market is afforded for their provisions. Many also of their active young men, bred to the sea, go out on board of these vessels, and make up any deficiency in the crews, especially of those destined for the northern fisheries.

2112. *The topographical details of Orkney* do not possess any peculiar attraction. Kirkwall, however, bears marks of the periods when it was a Danish capital, and a residence of the sovereign Earls of Orkney. There is a large and massive cathedral, in some parts very elegantly ornamented; also ruins of a king's castle, an earl's palace, and a bishop's palace. The town is ill built, but has of late been considerably extended and improved. It has a good natural harbour, unimproved however by art. Stromness has one of the best harbours in the kingdom, and since it was emancipated from the thralldom in which it had been held by Kirkwall, it has rapidly extended, and become the favourite resort of vessels which seek on this coast for shelter and refreshment. Near Stromness is that remarkable piece of antiquity the "standing stones of Stennis," which in magnitude and singular character almost rivals Stonehenge. Shapinsay, Stronsay, Rousay, Eday, Westray, Papa, and Sanday, are small islands stretching to the north-east. Barra and South Ronaldshay are towards Caithness; and to the west the long island of Hoy, which, differing from the rest, presents a series of bold and rugged promontories to the mariner who has passed through the Pentland Frith, and who, in quitting Hoyhead, plunges into the boundless waste of the Atlantic.

Fig. 210. Map of the Shetland Islands.

2113. *The Zetland or Shetland Islands*, called by the natives Hialtland, must close our survey of Britain. Though not, as imagined by the ancients, the remotest boundary of the habitable world, yet they form one of the boldest extremities of Europe, encircled by the illimitable extent of the Arctic and Atlantic oceans. Placed thus far north, and amid so wide a waste of waters, the climate of Zetland is cold, bleak, swept by furious winds, and deluged by torrents of rain. The surface is rugged, without being mountainous; it is every where penetrated, not by the mountain lakes of the Highlands and Isles, but by long lagoons with flat shores, called *voes*, by which even the largest islands are so intersected, that there is scarcely a spot in them two miles distant from the sea. The extensive mosses, and the trunks of trees dug out of them, prove that a vast

expanse was once covered with natural forests; but these are now totally eradicated, and the violence of the winds and sea-spray has rendered abortive every attempt to replace them,

so that the aspect of the country is now completely naked, scarcely producing even a shrub. The coasts are peculiarly steep, rocky, and bold, the rocks being hollowed into deep caverns, and broken into precipices and cliffs of the most varied forms. The aspect of these shores, against which the waves of the great surrounding ocean dash with almost perpetual fury, is equally grand and terrible. The author of "The Pirate" draws a most lively picture of these "deep and dangerous seas of the north, their precipices and headlands, many hundred feet in height — their perilous straits, and currents, and eddies — long sunken reefs of rock, over which the vivid ocean foams and boils, — dark caverns, to whose extremities neither man nor skiff has ever ventured, — lonely and often uninhabited isles, and occasionally the ruins of ancient northern fastnesses, dimly seen by the feeble light of the arctic winter." The dangers of the navigation, however, are considerably mitigated by the spacious and commodious havens, formed by the deep bays and *voes*, or by the sounds and channels, between different islands.

2114. *As to industry and produce*, the Shetland Islands remain in a low state. They contain about 20,000 acres of arable land, and nearly as many of good meadow; but this comprises little more than a twentieth part of the surface, all the rest consisting of waste or common, on which the horses, cattle, and sheep are turned out, to find pastures as best they may. The horses are of a very small size, with a huge mane, but active and hardy. The cows are equally diminutive, and give very little milk, but both the milk and the flesh are of good quality. The sheep are most numerous of all, being reckoned at seventy or eighty thousand; they are stunted, like the other animals, and their wool very scanty; but some of it is peculiarly fine, affording the material of almost the only manufacture of Shetland, and one of the finest in the world, — that of knit hosiery, of a texture so close, soft, and warm, as to render its use quite a luxury. The greatest branch of Shetland industry, however, is the fishery; not of herrings, but of cod and ling for salting and drying. All the coasts abound with these fish; and, within the last few years, a peculiarly rich and extensive bank has been discovered to the westward. At the proper season, fleets of boats issue from all the bays and *voes* to the *haaf* or deep-sea fishery, which is carried on, not without peril, at the distance of from twenty to thirty miles from the coast. The fishermen are supplied by the landlords with boats and implements, on condition of delivering to them the fish at a stipulated rate; and as their farms are held at will, they are, from this natural combination of circumstances, placed in a state of vassalage more complete, perhaps, than any other class in the United Kingdom.

2115. *The annals of Shetland* are Norwegian. Those islands, according to the earliest tradition, were peopled from Norway. In the ninth century they were conquered by Harold Harfager, or the Fair-haired, the most powerful and formidable of all the sea-kings of the north. The Norwegian sway extended for several centuries over all the Scottish islands; but in the Shetlands it was undisputed, till the cession of them, along with those of Orkney, as the dowry of a princess of Norway married to James III., in the end of the fifteenth century.

2116. *The topographical details of Shetland* are not of great magnitude. Lerwick, its capital, would in the Lowlands be considered rather a thriving village, ill and irregularly built, but improving. The opposite island of Bressay forms Bressay Sound, one of the finest harbours in the world, and the rendezvous of all the vessels destined for the north and the whale fishery. Off Bressay is the most remarkable of the rock phenomena of Shetland; the Noss (fig. 211.), a small high island, with a flat summit, girt on all sides by perpendicular walls of rock. The communication with the coast of Bressay itself is maintained by strong ropes stretched across, along which a cradle is run, in which the passenger is seated. The promontories of Sumburgh and Fitful Head, at the southern extremity of the Mainland, are also distinguished by the boldness of their aspect and the perils with which they threaten the mariner. Scalloway, notwithstanding its excellent harbour, and its importance in early times, has dwindled into an insignificant fishing village. The number of the Shetlands has been variously estimated, according to the gradations of islets and rocks included; but only about forty are inhabited. Of these, Yell and Unst, stretching northwards from the Mainland, are alone of any magnitude. The last, though the most northerly, is rather the most fertile of any, and distinguished by its numerous caves. Adjacent to Yell is Fetlar; on the east of the Mainland are Whalsay and Bressay; to the west,

NOSS ROCK, SHETLAND.

Burra, Housa, Frondray, Papa Stour, Mickle and Little Rhoe, all so close as to be little more than peninsulas. Considerably out at sea, Foula, a small rocky islet, faces the Atlantic, with high cliffs covered with numberless flocks of sea-fowl.

CHAP. IV.

IRELAND.

2117. *Ireland is a fine and extensive island*, situated to the west of England, and forming one of the three grand portions of the United Kingdom.

SECT. 1. General Outline and Aspect.

2118. *The greatest dimension of Ireland* is from Cape Clear, in $51^{\circ} 19'$, to Malin Head, in $55^{\circ} 23'$ N. latitude; making $4^{\circ} 4'$, or about 280 miles. The utmost breadth, if reckoned from the most easterly point of the county of Down (opposite Bur Island) to Dunmore Head in Kerry, will be $5^{\circ} 9'$, or 218 miles; but it is nowhere so broad under the same parallel of latitude. The island, according to Beaufort, contains more than 30,000 English

square miles, or nearly 30,000,000 acres; but, till the survey be completed, precision on this subject cannot be attained.

2119. *The surface of Ireland cannot on the whole be called mountainous*; its central districts composing one vast plain, which crosses the kingdom from east to west. It is, however, diversified by ranges of mountains, superior in extent, and, with the exception of those of Wales, equal in elevation, to any in England. Wicklow, in the vicinity of Dublin, may be classed as an alpine region. On the borders of Leinster and Munster, the Slieve-Bloom, the Knockmele Down, and the Galties, form long and lofty ranges, commanding an extensive view over the wide plains that stretch beneath them. All these, however, are much surpassed by the extreme south-west county of Kerry, which presents a complete chaos of lofty and rocky summits. The most elevated are those which enclose the beautiful and finely wooded lakes of Killarney, Mangerton and Macgillicuddy's Reeks, the last of which is considerably more than 3000 feet high. At the opposite or north-eastern extremity of Ireland, Antrim presents to the Scottish seas a barrier of rocky cliffs, less lofty, but of a very bold and peculiar character; precipitous, and formed into long columnar ranges; a phenomenon which the Giant's Causeway exhibits on a greater scale than any other spot in the known world. The Mourne mountains, a lofty granite range in the south of the county of Down; those of Carlingford, which extend into the county of Armagh; with considerable ranges in Tyrone, Derry, and Donegal, may dispute the pre-eminence with those of the south. In Connaught there are also some considerable detached mountains, of which Croagh-patrick in Mayo has been reckoned by some to exceed even Macgillicuddy's Reeks; but Ireland has no extended table lands like those which cover a considerable part of England. The most elevated part of the Bog of Allen, in that central point where the rivers divide, is not more than 270 feet above the level of the sea.

2120. *The rivers and bays of Ireland form a noble feature*, and would be the theatre of a most extensive commerce, did the regions through which they flow afford more ample materials. The Shannon is without a rival in the three kingdoms. It rises far in the north, from Lough Allen in the province of Connaught, and has a course of 170 miles, throughout the whole of which it is more or less navigable, the only obstruction which existed having been removed. Below Limerick it expands into an estuary about sixty miles in length, by which the largest vessels have access to that city. The Barrow is also an important river, which runs southward through the greater part of Leinster, receives from the west the Nore and the Suire, and finally forms the harbour of Waterford. The Boyne, so celebrated for the victory gained on its banks; the Foyle, which, after passing Londonderry, forms Lough Foyle; the Bann, which passes through Lough Neagh, and affords a flourishing salmon fishery; and the Blackwater, which terminates in the bay and port of Youghal, are also deserving of mention. The other rivers are rather numerous than of long course; but they almost all terminate in wide estuaries and *loughs*, which diffuse through Ireland the means of water communication, and afford a multiplicity of spacious and secure harbours. The western coast, in particular, exposed to the perpetual action of the waves of the Atlantic, has, according to Mr. Young's expression, been completely sawn into bays; which, if the country were in a more advanced state of improvement, would afford ample facilities to its commerce.

2121. *Lakes or loughs are a conspicuous feature in Ireland*, where this last name, like the similar one used in Scotland, is in many instances applied to arms of the sea. Lough Neagh is the largest lake in the United Kingdom, covering nearly 100,000 acres. Its banks are flat, tame, and in many places marshy and inundated. Lough Erne, also in Ulster, is divided into two reaches, the united length of which is about thirty miles, while its circuit includes a great variety of rich and ornamented scenery. Lough Foyle, Lough Swilly, and Belfast Lough, are properly bays. The Shannon forms several lakes, of which Lough Ree is the principal; and the whole of its course downwards from Limerick resembles more a lough or bay than a river. Connaught has several extensive lakes. That of Killarney, in the south, is famed, not for its extent, but for the singular grandeur and beauty of its shores. A fuller description of this and some others now mentioned will be found under the local section.

SECT. II. *Natural Geography.*

2122. *The Botany and Zoology of Ireland*, as connected with that of the United Kingdom, having been treated of under the head of England, the subdivisions of this section will be confined to Geology.

SUBSECT. 1. *Geology of Ireland.*

2123. *The geology of this important part of the British empire* is not so well known as that of Great Britain. To a distinguished scholar of the Freyberg school, Mr. Weaver, we are indebted for the most interesting series of geological observations; Hamilton, Richardson, Stephens, Berger, Griffith, Sir Charles Giesecké, Buckland, Conybeare, and

north of them, extending westward across Monaghan into Cavan, and on the north-east to the southern cape of Belfast Lough and the peninsula of Ards. It is worthy of remark that the points of the coast of Scotland, directly opposite the peninsula of Ardes, where the greywacke terminates on the Irish side of the north channel, present in the neighbourhood of Portpatrick, and through the great alpine band which traverses the south of Scotland, and terminates on the east coast at St. Abb's Head, the same transition rocks. Hence it is probable that the great southern high land of Scotland was formerly joined with the transition hills of the Mourne mountain group by a ridge of land extending across the Channel from Scotland to Ireland. In this district there are some patches of mountain limestone and of old red sandstone; at Newton Ards, at the head of Lough Strangford, there is a deposit of old red sandstone.

2126. 2d system. *Primitive chain of Londonderry.* This mountain group rises at the distance of about 30 miles to the north-north-west of the external chains of the first system. It forms a large tract, bounded on the east by the river Roe, on the south by a line extending from Tubermore by Omagh to Ballentra, and on the west and south by the ocean; thus including the counties of Londonderry and Donegal. One of the highest points in this district is Sawell, said to be 2257 feet above the level of the sea. This great tract of country is principally composed of mica slate, with various subordinate beds, as limestone, quartz, &c. On the eastern bank of the Roe, these mica slate hills and mountains are succeeded by a range of secondary hills covered by a great platform of secondary trap, and forming a part of the third system of hills, afterwards to be described. These newer rocks repose upon and conceal the mica slate in the eastern part of Derry, but the mica slate again emerges from beneath this covering, after an interval of about 30 miles, on the north-east coast of Antrim, and rises into hills, which break down abruptly towards the coast between Tor Point and Cushenden Bay. The mica slate rocks on this part of the Irish coast may be considered a continuation of those that occur on the opposite coast of Scotland at the Mull of Cantyre, or, on a more general view, as a continuation of the great Grampian range, which may, in this way, be said to extend from the north-east coast of Scotland to the western shores of Ireland, on the coasts of Donegal. In the eastern part of Tyrone, which intervenes between the transition mountains and the mica slate mountains, a coal formation occurs associated with that kind of limestone which is usually found below coal in Great Britain. The position of this coalfield offers another analogy with Scotland, where the space between the southern and northern mountains is principally occupied by rocks of the coal formation.

2127. 3d system of mountains. *The Trap group.* This group may be described as separated into two chains, bounding on the east and west the trough or valley through which the river Bann flows from Lough Neagh to the ocean. The eastern chain lies in the county of Antrim, being comprehended between the valley of the Bann and the northern channel. It presents an abrupt declivity towards the sea, falling with a gentle slope towards the west, in which direction the beds composing its mass incline. The hills of which it is composed are generally detached and distinct, yet so closely grouped together, that there can be no impropriety in considering them as parts of a single chain. According to Dr. Berger, Knock-lead, in the northern extremity of the chain, is the highest summit: it rises 1820 feet above the level of the sea; but the basis of this hill is occupied to the height of 500 feet by primitive mica slate rock, leaving only 1320 feet for the thickness of the secondary strata peculiar to this system. Diris Hill, near the southern extremity of the chain, is wholly composed of secondary strata, and attains an elevation of 1475 feet above the level of the sea; it is situated about two miles to the west of Belfast. The western part of the chain included between the Roe and the Bann forms the exact counterpart of the former; but the strata here dip nearly in a contrary direction, viz. towards the north-east; the fall of the hills being gradually in this direction, while they front the west and south with abrupt and precipitous cliffs. Cragnashoack, at the southern extremity, rises 1864 feet above the sea, and is the highest summit of the group. The geological nature of this third system is very different from that of the two former; all the principal formations belonging to the secondary class of rocks. These rocks are partly Plutonian and partly Neptunian. The Neptunian rocks are generally covered with an enormous mass of secondary trap, which appears to attain its greatest thickness on the north; the trap cap of Beny-Avenagh, the most northern summit of the western chain, measuring more than 900 feet: the average depth of this superimposed mass may therefore be estimated at 545 feet, and its superficial extent at 800 square miles. The trap rocks are greenstone, basalt, amygdaloid, wacke, and red bole; occasionally associated with them, forming isolated tracts, as in the Sandybrea district, there are porphyries of different kinds, as pitchstone and pearl-stone porphyries. The amygdaloid and also some of the other rocks of this series contain calc spar and white calcedony, semiopal, felspar, and steatite, or serpentine. The basalt contains olivine. Iron pyrites is a mineral frequently disseminated in the greenstone. Wood coal occurs in seams varying from two inches to four or five feet in thickness, alternating with trap rocks, near

Ballentoy; also in the cliffs of Portnoffer on the east of the Giant's Causeway, at Killymorris near the centre of the trap area, and at Portmaoc, and other places on the eastern shore of Lough Neagh.

2128. *Veins of trap.* Trap veins exhibit many interesting phenomena, particularly in their passage through chalk, which they sometimes convert into a kind of marble. They traverse not only the Neptunian strata, as chalk, lias, and coal formation, but also trap itself. The most interesting and splendid displays of the trap rocks occur at the Giant's Causeway and Fairhead, so well known to travellers; and the cliffs of Kenbaan exhibit very interesting displays of the commingling of the trap and chalk.

2129. *Underneath and sometimes intermingled with this vast mass of trap* are the following Neptunian formations: — *Chalk*, which is frequently very compact, and sometimes, as where in immediate contact with the Plutonian rocks, changed into a granular limestone resembling marble: the average thickness does not amount to more than 200 feet. Underneath the chalk occurs the deposit known under the name *mulatto stone*, the *green sand* of English geologists, which is a calcareous sandstone with disseminated spots of green earth. The next member of the secondary series is the oolite, which, however, does not appear any where in this district; for the green sand is found lying upon the *lias limestone*. Underneath the lias occur beds of *red and variegated marl*, *variegated sandstone* with gypsum, and from these issue *salt springs*. These four formations, which, together with the trap, form the whole mass of the hills belonging to the third system, cannot be estimated as possessing a less average thickness than from 800 to 1000 feet. The whole system appears at the north-eastern and south-western extremities to repose upon the *coal formation* and its accompanying rocks, and these on the transition or primitive rocks.* Coal occurs in Tyrone, at Coal Island and Dungannon, and in Antrim, near Ballycastle. Of these, the collieries at Ballycastle, which occupy an extent of not less than one English mile along the coast, are the most considerable. They have been long wrought, and were once in a more prosperous state than at present, as they used formerly to send from 10,000 to 15,000 tons of coal to the market yearly; whereas now the quantity exported does not amount to more than 1500 or 2000 tons. The coal of these districts is almost entirely what Berger calls slate coal. In one of the works, however, in Coal Island, a bed of cannel coal, six feet thick, is said to have been wrought.

2130. *The most remarkable minerals of the alluvial kind found in this part of Ireland* are the fossil woods of Lough Neagh, a sheet of water 132 feet above the level of the sea, about nineteen miles six furlongs long from N.W. to S.E., and forty-five feet deep at its centre. The wood is silicified, and in some specimens one extremity will be petrified, while the other remains in a ligneous state. The oak, the holly, and the hazel appear to have been the trees thus affected. It occurs in alluvium in the neighbourhood of the lake.

2131. (3.) *Connaught Coal District.* This district occupies a portion of the counties of Roscommon, Sligo and Leitrim, in the province of Connaught, and part of the county Cavan in the province of Ulster. Lough Allen, situated near the head of the river Shannon, forms a basin in the centre of the district.

2132. *A range of primary mountains*, varying in breadth from three miles to a quarter of a mile, extends from Foxford in the county of Mayo, to Colooney in the county of Sligo, and terminates two miles to the north-east of Manor-Hamilton, which may be viewed as the base on which the newer formation of this part of Ireland rests. This range of country is principally composed of mica slate, with some subordinate rocks. Benbo Mountain, near Manor-Hamilton, 1403 feet above the sea, may be cited as exhibiting an interesting display of the various primitive rocks. The summit, and about 800 feet immediately below it, are composed of a fine granular granite: the granite is covered on both sides of the mountain with gneiss, dipping in the direction of its declivity at an angle of 50°. At the base of the mountain, mica slate, with garnets, hornblende rock and hornblende slate, are seen. Large blocks of beautiful syenite, also of serpentine with embedded garnets, were found in a stream at the base of the mountain near Lurganboy. The western side of Benbo is traversed by a vein of copper pyrites, which was formerly wrought, but apparently to no great extent. Veins of iron pyrites also occur there.

2133. *Resting upon these old rocks in many places*, we observe the first or old red sandstone formation. A tract of this sandstone extends in Roscommon from west to east, from Derrynalieve to Cashcarrigans, and in greatest breadth in a southerly and northerly direction, from Leitrim to the neighbourhood of Drumshambo. Resting upon this sandstone, forming the base of the coal district, and encircling it, is the mountain or carboniferous limestone. This limestone exhibits the usual character of the formations. The coal formations rests upon the limestone, and is the uppermost or newest of the secondary deposits met with in this part of Ireland. The external aspect of this coal district is described as being hilly and dreary, and as extending in greatest length in a north and south direction, from Down Mountain to Kedduie,

* Patches of old red sandstone occur on the east coast between Ballygelly and Glenarm Bay; and also on the same coast to the southward of Gerron Point.

about sixteen miles, and in greatest breadth from the hills above Swadlinbar to Killargy, sixteen miles. The area of the whole coal country within the edge of the limestone is about 114,000 Irish acres; exclusive of Slieve Russel, which is detached from the great district by the limestone valley of Swadlinbar. The centre of the coal district is occupied by Lough Allen, and different tributary streams besides the Shannon, which flow into the lake, run in straight but deep valleys, and divide the district into *four parts*. The rocks which form the coal series in the Connaught coal district are similar to those met with in other coal-fields. Besides coal, which is the *black bituminous species*, the formation contains sandstone flag, slate clay, bituminous slate, clay ironstone, and fire clay. Some kinds of the coal afford in the 100 parts, 71.42 carbon, 23.37 bitumen, and 5.21 grey ashes. The entire produce per annum of the collieries of the southern and western divisions of the Connaught coal district is about 1300 tons. In these divisions there are but three beds of coal, only one of which is worth working. Yet this single bed, though but three feet in thickness, is, from its great superficial extent, sufficient to supply the county with fuel for many centuries; the estimated quantity of coal in the southern and western divisions being upwards of 30,000,000 tons.

2134. *The coal in the northern and eastern divisions of the district is also bituminous.* It occurs in beds which are by no means so considerable, nor is the coal so good, as in the western and southern divisions.

2135. *Iron-works.* The beds of clay ironstone that occur in all parts of the Connaught coal district appear, at an early period, to have attracted the attention of miners; and works, on a very small scale, called *bloomeries*, were carried on in various parts of the adjoining country, as long as any wood remained to supply them with charcoal: at that time coal had not been discovered. The iron-works of Drumshambo were the last that continued to be worked; they were given up about the year 1766. The ironstone to supply them was chiefly collected from the eastern shore of Lough Allen. The ironstone was conveyed by boats to the works; and charcoal, from the extensive woods which at one time flourished in all the valleys, was conveyed by the same means. Limestone for smelting the iron was quarried close to the works. The smelted iron from Drumshambo works was carried to the neighbouring village, where it was forged into bars. In 1788, iron-works were established at Avigna. At that time the practicability of smelting iron with charred pit coal, or coke, instead of wood charcoal, was well known in England and Scotland. The Avigna iron-works, being the only ones ever erected in Ireland to smelt iron with pit coal, attracted great attention; and their want of success has in consequence been regretted. From a minute examination made on the spot, the quality of all the requisite materials was found excellent of their kind; and, although the cost of each, when delivered at the works, was greater than might have been by better management, still cast iron of the very best quality could have been manufactured at Avigna for 3*l.* 4*s.* per ton; while cast iron, called pig-iron, greatly inferior in quality, sells in Dublin at the rate of 10*l.* per ton. In better times these mines will be resumed.

2136. (3.) *East of Ireland.* This district extends nearly 100 miles from north to south, and between sixty and ninety miles from east to west, comprehending about a third part of the island. It is bounded on the east by the Irish Channel, on the south and west by the mountains which confine the Suire and the Shannon, and on the north by the clay slate hills of Louth and the mountain limestone hills of Meath, the clay slate hills of Cavan and the mountain limestone of Longford, and by a line produced from thence to the bay of Galway. In the landscape of Ireland there is one very remarkable feature, which cannot fail to strike every observer: in traversing most parts of the island, we meet with ranges and groups of bold mountainous and hilly tracts, in some degree isolated, while the interval between them is generally occupied by a surface that appears nearly level, when viewed on the great scale, but which is found, on a nearer view, to present a gently waved outline: a considerable expansion of the plain occupies the central counties of Ireland, and extends across the island from Dublin Bay on the east, to Galway Bay on the west; and in general, where a similar plain surface occurs, the immediately subjacent rock is mountain limestone; to the abundance of which mineral, next to the mild temperature and general moisture of the climate, the soil of Ireland is probably more indebted for its superior fertility than to any other cause. It is a fact deserving of notice, that, with the solitary exception of Wicklow, there is no county in the island in which limestone rock, either secondary, transition, or primary, is not to be found; but the primary limestone appears in a great measure to be confined to the counties of Sligo and Galway on the west, and to Donegal, Derry, Tyrone, and Antrim on the north.

2137. *In this district* mountainous and hilly tracts arise above the surface of the limestone plain, on the east, the south, the west, the centre, and the north. The eastern chain extends from the north side of Dublin Bay to the confluence of the Barrow with the Suire on the south. The highest point is Lugnaquilla, which is 3070 feet above low water-mark in Dublin Bay. It consists almost wholly of primitive and transition rocks, of which the follow-

ing species occur: granite, mica slate, quartz rock, clay slate, greywacke, trap and porphyry. Metalliferous minerals are wanting on the west side of the granite chain, but abound on the east side. In the granite and mica slate districts there are veins of galena or lead glance; of these the most considerable are in Glenmalur; in the clay slate tract eleven different metallic substances have been met with, viz. gold, silver, copper, iron, lead, zinc, tin, tungsten, manganese, arsenic, and antimony.

2138. *Native gold* occurs in the Ballinvalley streams at Croghan Kinshela: it was accidentally discovered, and at first was kept secret; but being divulged, almost the whole population of the immediate neighbourhood flocked in to gather the precious metal, actually neglecting, at the time, the produce of their own fields: this happened about the autumn of the year 1796, when several hundreds of people might be seen daily assembled, digging and searching for gold in the bank and bed of the stream. Considerable quantities were thus collected, this being, as it afterwards proved, the most productive spot; and the country people remained in the undisturbed possession of the place for nearly six weeks, when government determined to commence operations. Regular steam-works were soon established; and up to the period of the rebellion in May, 1798, when the works were destroyed, government had been fully reimbursed its outlay, and left a surplus in hand. In the year 1801, regular mining was commenced, but which, on the whole, did not lead to any important results; and after a time, as no gold was found in the solid strata, and as the alluvial deposits afforded no return sufficient to defray expenses, the working was given up. The gold of Croghan Kinshela occurred in grains and masses from the smallest size to lumps of considerable weight; one piece weighed twenty-two ounces, another eighteen ounces, a third nine ounces, and a fourth seven ounces. The gold was found in alluvium, accompanied with other metallic substances, as magnetic iron ore, iron glance, red iron ore, brown iron ore, iron pyrites, *tinstone*, wolfram, grey manganese ore, and fragments of quartz and chlorite. In some specimens the gold was observed ramified in slender threads through the wolfram, and in others incorporated with iron ochre: some of the gold was crystallised in octahedrons, and also in the elongated garnet dodecahedral form.

2139. *The total amount of gold* collected by government amounted to 944 ounces, 4 pennyweights, and 15 grains; of which 58 ounces, 16 pennyweights, and 1 grain were sold at 4*l.* per ounce, amounting in value to 236*l.* 16*s.* 8*d.* The remaining 885 ounces 8 pennyweights, 14 grains was melted into ingots, which weighed 848 ounces, 18 pennyweights, 5 grains: hence the loss in melting was 36 ounces, 10 pennyweights, 9 grains; or nearly 4½ per cent., which arose from the disseminated particles of grain. The ingots produced from 21½ to 21¾ carats of fine gold, the alloy being silver; and they were bought by the Bank of Ireland at prices varying from 4*l.* 0*s.* 6*d.* per ounce to 4*l.* 2*s.* per ounce, amounting in value to 3438*l.* 17*s.* 3½*d.* Hence the aggregate value of the native and ingot gold was 3675*l.* 7*s.* 11½*d.* Native gold was also found in Croghan Moira mine, about seven miles distant from the former mountain, but in small quantity.

2140. *The copper mines of Cronbane and Tigrony*, in this district, are situated in clay slate and quartzose clay slate. The ores, which are copper pyrites and black copper ore, are associated with iron pyrites, and rarely with galena; and auriferous silver occurs in beds in the slaty strata. In the twelve years ending in 1799 the mines of Cronbane had yielded 7533 tons of ore, which produced 670 tons 11 cwt of copper. In the next twelve years, ending in 1811, the produce was 19,342 tons 13 cwt. of ore; yielding 1046 tons 10 cwt. of copper. The mineral waters flowing from the mines are impregnated with blue vitriol or sulphate of copper. These waters are received into tanks, in which the muddy particles are allowed to subside. The clear waters are then passed into pits filled with plate and scrap iron, which occasions a precipitation of the copper. In this way 442 tons 11 cwt. of this precipitated copper (mixed with oxide of iron) have been obtained, which sold on an average for 27*l.* 8*s.* 9*d.* per ton, being in aggregate value 12,126*l.* 18*s.* 1½*d.*; while the consumption of iron was only 429 tons 14 cwt., or less than one ton of iron to the ton of precipitate; being in aggregate value 2620*l.* 18*s.* 2*d.* Sulphur was extracted on the spot from the copper pyrites, and during the war sold at the rate of between 20*l.* and 30*l.* per ton.

2141. *The other tracts of this district* are composed of secondary rocks, more or less deeply covered with diluvial and alluvial deposits. The secondary rocks are *old red sandstone*, *mountain limestone*, (or, as it is called in Ireland, Irish limestone,) and the *coal formation*. Of these formations the mountain limestone is by far the most abundant; indeed, with the exception of the counties of Derry and Antrim in the north, and Wicklow in the east, there is no county in the island in which it does not prevail more or less. The coal formation, the most interesting of the secondary deposits, occurs in what is called the *Leinster coal district*. The sandstone, slate, ironstone, clay, and coal, which constitute the series, alternate with each other, and the whole rests on the mountain limestone, and is frequently disposed in the basin shape. The coal of this district is *glance coal*, the blind coal of miners, the anthracite of French geologists, the Kilkenny coal of some authors (so named because the

town of Kilkenny is situated in this coalfield). Fire-damp is unknown throughout the Leinster coal tract.

2142. *The most interesting alluvial phenomena* are those exhibited by the limestone gravel, the granite blocks, and the vast peat bogs. The great limestone field abounds in hillocks and ridges of limestone gravel. Sometimes these ridges appear like regular mounds, the work of art, forming a continued line of several miles in extent. That which passes by Maryborough, in the Queen's County, is a remarkable instance of this kind; and similar mounds, hillocks, and ridges occur also in the counties of Meath, Westmeath, Kildare, Carlow, and other portions of the limestone field, in which the limestone gravel and sand frequently exhibit a stratified arrangement, the alternate beds being very distinct from each other. The inequality of surface thus produced, as Mr. Weaver remarks, seems to have occasioned the formation of those extensive tracts of peat bog which cover so considerable a portion of the limestone plain of Ireland.* The natural course of springs and streams being obstructed, stagnant lakes and pools of water were formed; thus promoting the growth of those aquatic reeds, grasses, and rushes, which, by their constant increase and decay, appear to compose the mass of the bogs of Ireland. In this manner it is conceivable that shallow lakes may in process of time have become entirely filled with peat; and that peat bogs may thus have gradually acquired a convexity of surface, or at least that greater declivity by which their borders are distinguished. The average depth of these bogs is commonly from sixteen to twenty-five feet, but some reach from thirty to thirty-five feet, and the extreme depth observed is forty-seven feet. In the same manner we may conceive the gradual growth of peat bog to have successively extended from the higher regions to the flanks, and thence to the feet, of mountains. That fallen forests were not the primary origin of these peat bogs seems evident from the circumstance that two and even three successive growths of trees have been observed at different depths in a section of the same bog. In these instances, the trees lie horizontally, frequently crossing each other, and either attached to their roots or broken over; and in the latter case the stumps usually stand erect where they grew. The prostration of trees, however, may to a certain extent have acted as an auxiliary in promoting the growth of peat bogs; and this prostration appears in general to have taken place either from natural decay, or from trees possessing little hold of a wet spongy soil having been overturned by storms. This may partly account for trees of all ages being found in the bogs of Ireland, whether these bogs be situated in plains, or form the immediate cover of high mountain tracts. That Ireland was once covered by extensive forests, even in the more elevated chains, can scarcely be doubted; for, independently of the evidence preserved in the peat bogs themselves of the growth of trees, numerous stools of trunks long since cut down yet remain in most of the mountain districts, which require only protection from cattle to produce vigorous shoots. The universal destruction of the forests of Ireland is principally to be attributed to the general introduction of iron furnaces, as the most profitable mode of consuming the timber, then a material esteemed of little value; and hence the almost total neglect of coping those tracts in which the woods had been felled. Remains of the ancient charcoal hearths are still plainly to be distinguished by their verdure and level circular surface, scattered over the rapidly shelving sides of Glendalough, Glenmalur, and other glens, when we look down upon them from a considerable elevation. The marl beds, so frequently met with in these peat bogs are curious in a zoological view, from their occasionally containing remains of that splendid animal the fossil elk. But the remains of the extinct species are not, according to Mr. Hart, confined to the marl, but occur also in the gravel; and the late Mr. Edgeworth observed the remains of the red deer in the same marl as that which contained the extinct species.

2143. (4.) *South of Ireland.* Under this division we comprise the counties of Cork, Kerry, Clare, Waterford, Tipperary, and part of Galway.

2144. *This mountainous, hilly, and diversified region* is chiefly composed of chains having generally a direction from east to west, and attaining their greatest elevation in the mountains of Kerry, where Gurrane Tual, one of Macgillicuddy's Reeks, near Killarney (the highest land in Ireland), is 3410 feet above the sea. The rocks in this elevated county are chiefly of the transition class: they decline gradually towards the north, and finally pass under the old red sandstone and mountain limestone of the midland counties. The following may be considered a general estimate of the geognostical relations of the south of Ireland:—

2145. *Transition rocks.* In Kerry, the transition strata range from east to west, and dip to the north and south, with vertical beds in the axes of the ranges: the strata, as they diminish in inclination on each side, form a succession of troughs. The rocks are chiefly Neptunian, the Plutonian being comparatively rare. The Neptunian are either simple or compound; the simple are *clay slate, quartz rock, hornstone, Lydian stone, and limestone*: the compound are, *greywacke, greywacke slate, sandstone*. The Plutonian rocks are *greenstone and porphyry*. Organic remains occur in the limestone, slate, and greywacke, but more frequently and abundantly in the limestone than in the other rocks. In Kenmare

* Peat is estimated to extend over a tenth of the whole island.

these fossils consist of a few bivalves, and some crinoidal remains; and these also are most numerous in the Mucruss and Killarney limestones. At the foot of the Slieve-meesh range this limestone includes *asaphus caudatus*, *calamine macrophthalma*, with *orthoceratites*, *ellipsolites ovatus*, *ammonites*, *euomphalites*, *turbinites*, *neritites*, *melanites*, and several species of *terebratula*, *spirifer*, and *producta*. Near Smerwick harbour similar organic remains are abundant in slate and greywacke, together with *hysterolites*, and many genera of *polyparia*.

2146. *Transition coal.* All the coal of the province of Munster, except that of the county of Clare, is referable to the transition class. At Knockasartnet, near Killarney, and on the north of Tralee, there are three beds of glance coal, alternating with strata of greywacke and slate. In the county of Cork this glance coal is more abundant, particularly near Kanturk, extending from the north of the Blackwater to the Allord. The ravines of the latter river, and various other defiles, expose clay slate, greywacke, talc, and sandstone, in nearly vertical strata, ranging from west to east. This transition tract extends to the river Shannon on the north-west. As the strata range from west to east, in a series of parallel narrow troughs, the strata exhibit great variety of inclination, dipping rapidly either to the north or south, and becoming horizontal between the ridges. The glance coal is raised in sufficient quantities for the purpose of burning the limestone of the adjacent districts; the most considerable collieries, those of Dromagh, have yielded 25,000 tons yearly, at from 10s. to 15s. per ton.

2147. *The coal and the strata* with which it is accompanied abound with impressions of *equisetæ* and *calamites*, and afford some traces of *fucoides*. Beds of glance coal also occur in the county of Limerick, on the left bank of the Shannon, north of Abbeyfeale, and at Longhill; and on the right bank of the river at Labbasheada. The transition rocks of Kerry and Limerick extend into Cork and Waterford.

2148. *Mines.* Copper mines occur in limestone in Ross Island in the lake of Killarney. In the county of Cork, there are copper mines at Allihies, Audley, and Ballydehol; and others, producing lead, at Doneen and Rinabelly. The mine at Allihies is one of the richest mines in Ireland; it was discovered only in 1812, and has already yielded more than 2000 tons of copper ore annually. The ore occurs in a large quartz vein, which generally intersects the slaty rocks of the country from north to south, but in some places runs parallel to the strata. It is remarked that all this portion of the county of Cork indicates a very general diffusion of cupreous particles, so much so that, in the year 1812, there existed a cupriferous peat-bog on the east side of Glandore harbour, forty or fifty tons of the dried peat producing when burnt one ton of ashes, containing from ten to fifteen per cent. of copper. The lead mines of Doneen and Rinabelly are in slate.

2149. *Coal formation of Clare.* The transition clay slate of this county is bordered by a zone of old red sandstone, to which succeeds, in ascending order and conformable position, the mountain limestone and coal formation, both of which occupy flat and undulating hills, and the strata are nearly horizontal. The best sections are seen in the cliffs on the west coast, where bituminous shale, slate clay, sandstone, and sandstone flag rest upon limestone. Coal, however, is of rare occurrence, and when found is of indifferent quality.

2150. *As in every other part of Ireland, the district abounds with alluvial deposits.* In regard to the distribution of the older of these, or the diluvium in the south of Ireland, it is remarked, — 1. That boulders, gravel, and sand, derived from the transition rocks, are distributed along the borders and sides of the mountains in Kerry. 2. In a small district of Limerick and Tipperary, situated between the Gaultees and Slieve-na-muck, the rolled masses consist not only of portions of contiguous rocks, but contain also porphyry, which is not to be found *in situ* near the vicinity of Pallis Hill. 3. In the peninsula of Nenville, near Galway, the surface of the mountain limestone is strewn over with numerous boulders of red and grey granite, syenite, greenstone, and sandstone, which must apparently have been conveyed from the opposite side of the bay of Galway.

SECT. III. *Historical Geography.*

2151. *The earliest inhabitants* of Ireland may undoubtedly be regarded as the original stock from which the native race now existing has sprung; for that country, though subdued, has never been exposed to those desolating migratory inroads which have changed the face of the rest of Europe. This race, by the language still spoken, appears to have been Celtic. It is highly probable that the Carthaginians may have founded colonies there; this conjecture being much supported by the remarkable circumstance, that a fragment of the Punic language preserved in Plautus coincides almost exactly with the modern Irish dialect.

2152. *The Romans*, in occupying all Britain, could not fail to acquire much information relative to Ireland; and accordingly we find that the map of that country by Ptolemy is less defective than the one which he gives of Scotland. Tacitus even mentions the scheme

formed by Agricola to conquer Ireland, that every tempting image of liberty might be removed from the view of the Britons. The pressure of more urgent concerns prevented the execution of this sweeping scheme of subjection; and no monuments of the Romans in Ireland give intimation that their mighty empire ever extended over any of the boundaries of *Ierne*. About the fourth century, we find Ireland bearing the name of Scotland, from the leading people on its eastern shore, who, afterwards passing into Argyle, and making themselves masters of all Caledonia, communicated to it the name of Scotland, finally withdrawn from the country to which it originally belonged.

2153. *The Danes*, during the height of their power, from the ninth to the twelfth centuries, not only ravaged but possessed almost the whole eastern coast of Ireland, making Dublin their capital. Before this time Ireland had been converted to Christianity, and a number of celebrated monasteries had been founded, the tenants of which were distinguished, even over Europe, for their piety and learning.

2154. *The English sway* commenced in 1170. Richard Strongbow, earl of Pembroke, as a private individual formed the first settlement; but Henry II. soon assumed the title of "lord of Ireland." The range of dominion was long restricted to a portion of the kingdom enclosed within what is called the English pale, without which the Irish remained still under the rule of their native chieftains. Henry VIII. assumed the title of "king of Ireland," but without any material extension of his authority over that kingdom.

2155. *The Irish massacre* was a dreadful outrage, to which attachment to popery and zeal for national independence united in impelling a proud and fierce people. Forty thousand English settlers are supposed to have perished, and the rest were driven into Dublin. Cromwell, however, afterwards crossed the Channel, and made cruel reprisals; he took the principal fortified towns, and reduced Ireland under more full subjection than ever. Yet the disposition of the people remained the same; and when James II. was driven from the English throne, he was received with enthusiasm in Ireland, and became for some time its master. The battle of the Boyne, followed next year by that of Aughrim, decided the fate of the empire, and more especially of Ireland, which then felt for the first time the miseries of a conquered country. The estates of many principal native proprietors were confiscated; and William, who introduced into Britain the system of full toleration, adopted an opposite code with respect to Ireland. The Catholics were deprived of all political privileges; they were rendered incapable of holding any office or employment in the state; they were debarred even from holding land, from devising property, and from exercising other important functions of civil society. Under these severities they pertinaciously retained their political attachments together with their religious creed; and a continual ferment prevailed, which broke out from time to time into partial rebellions.

2156. *The gradual emancipation of Ireland* commenced at the period of the American war. Till that era England had denied to her the right of trading directly with any foreign nation; and had compelled her to export and import every commodity through the channel of Great Britain. The extremity, however, to which Britain was reduced, when all the leading powers of Europe leagued with America against her, enabled the Irish to place themselves in a formidable attitude; and by forming armed associations, and adopting other threatening measures, they induced parliament to grant them free trade with all nations. From this time also the most obnoxious of the restrictions on the Catholics were gradually repealed, or fell into disuse; and before the end of last century, they had obtained almost every political privilege, except that of sitting in parliament, and of holding the very highest offices of state. The propriety of conceding these also became one of the leading questions which long divided the public mind.

2157. *A very formidable rebellion* broke forth, in spite of these concessions. The French revolution, which caused a general ferment in Europe, was intensely felt throughout Ireland. A society was formed of "United Irishmen;" and secret meetings were held, having in view the entire separation from England, and the formation of the kingdom into an independent republic. The vigilance of government, and the failure of the French in their attempts to land a force of any magnitude, prevented matters from coming to the last extremity, till 1798, when a violent insurrection arose in four of the counties nearest Dublin. The rebels, though zealous and brave, being without discipline, were routed in successive encounters with much inferior bodies of regulars and militia; and being unsupported by French aid, were completely put down in a few months. The exasperation, however, produced by the tragical events of this short period continued long to rankle in the minds of the Irish, and to aggravate the evils under which they laboured. To soothe this irritation, another expedient was employed, which materially affected the situation of Ireland.

2158. The difficult and reluctant *union of the two kingdoms* was effected in 1800 by Mr. Pitt. Ireland gained thus considerable commercial advantages; and, from the example of Scotland, it was hoped that a gradual tranquillity would be the result. This expectation has not yet been fulfilled. The peasantry of the south, inflamed by national jealousy, by religious animosity, and by the severe privations under which they labour, have continued,

if not in open rebellion, at least in a state of turbulence constantly tending towards it; and their discontents have been increased by the indiscreet zeal of the Protestant party.

2159. *The bill for Catholic emancipation*, so unexpectedly introduced, in 1828, by the Duke of Wellington, and carried after such a violent ferment of parties, has made a remarkable change in the political constitution of Ireland. The political disabilities under which the Catholics had hitherto laboured have been finally removed. They are made admissible to the highest offices of state, with the exception of that of lord chancellor; an exclusion decided upon, not so much on account of the dignity of that office, as the extensive church patronage attached to it. Roman Catholics are also made admissible to sit in both houses of parliament, and to every other political privilege enjoyed by their fellow countrymen.

SECT. IV. *Political Geography.*

2160. *The political evils* under which Ireland labours will sufficiently appear from the foregoing survey of her history. From the earliest times she has been in the situation of a conquered country, without ever becoming reconciled to the yoke, or assimilated to the ruling nation. Within the last two centuries, her devoted adherence to a religion which had been renounced by her rulers, has had a most fatal tendency, which we may however hope to see much mitigated by the healing measures that have now been adopted. In consequence, also, of repeated scenes of rebellion and forfeiture, by much the greater part of the lands are in the possession of English and Protestant proprietors, who, having no natural influence over the occupiers of their estates, hold their place only by the hated tenure of dominion and law. Being connected with the country by no natural ties, and attracted by the superior brilliancy of the English and French capitals, most of them quit Ireland, and become habitual *absentees*. When the Scottish Highlanders arrayed themselves against the government, they acted under the influence of a few leading chiefs, whose interests and passions afforded a lever by which the people could be moved. But the Irish people, deprived of any such guidance, chose their leaders from among themselves, or from those who courted their favour by fostering all their national propensities. Secret associations, party badges, mysterious names, have exerted an influence over their minds, the extent and nature of which it is impossible to calculate.

2161. *Ireland, like Scotland, has been united to England*; yet it retains somewhat more of the aspect of a separate kingdom. A lord lieutenant still displays a portion of the state and exercises some of the functions of royalty. He has not only a household establishment, but a chancellor, a secretary, and other ministers of state. The courts of justice, and the different orders of magistracy, are nearly on the same footing as in England; yet they have not the reputation of exercising their functions with quite the same dignity and impartiality. The violence of party spirit acts upon judges, and still more upon juries; and in the country, the absence of great proprietors, and the want of any middling class, render it difficult to find materials for a respectable and effective magistracy. Ireland sent to the Imperial parliament 100 members of the House of Commons, of whom 36 were for cities and boroughs, and 64 for counties, which latter sent two members each. The large proportion of this latter class was expected to render the representation more respectable; but, unfortunately, the low qualification required, amounting only to 40s., enabled the great proprietors to split votes among their numerous little tenantry to such an extent as almost to produce universal suffrage. The very system of letting farms on leases for lives, which confers the right of voting, extended that right to almost every tenant. This could scarcely be said to confer the real right of suffrage, as the dependence of the tenants was almost always such as to enable the landlord to dictate their vote; though in late elections, the influence of the priests was in several counties successfully exerted. To remedy these evils, the same act which removed the disabilities of the Catholics, raised the qualification of freeholders in Ireland from 40s. to 10l. a year, and thus reduced them to less than a third of their former number. Many also of the principal boroughs, as Belfast, Wexford, Cashel, Sligo, Dundalk, Enniskillen, were entirely close, the members being chosen by twelve self-elected burgesses; while, in others, the whole ground on which a borough stood belonged to the nearest great proprietor. The consequence was, that an oligarchy, formed by the possessors of those vast properties into which the greater part of Ireland is divided, held an almost unlimited sway over the country. Previous to the union, the influence of the three houses of Beresford, Ponsonby, and Foster was such, that the aid of one, and, if possible, two of them, was necessary for carrying on the measures of government. That influence, however, has been on the decline, and there is no prospect of its renewal.

2162. *The Reform Bill* gave to Ireland only five additional members, and it made no material change in the returning boroughs; but, by placing the election in the hands of all householders paying 10l. annually, it rendered those nominations open which had formerly been made by the small number of individuals composing the corporation.

2163. *The naval and military force* of the empire in general defends Ireland. There is a commander of the forces resident in Dublin; acting, however, under the orders, not of the lord

lieutenant, but of the British commander-in-chief. The number of regular troops stationed at different points varies according to political circumstances, but unfortunately must always be considerable.

2164. *The revenue levied in Ireland, notwithstanding the rigour with which she has in some respects been treated, has never borne the same proportion to her natural resources as that of England. The rates in all the principal articles of consumption have been lower. The tax on hearths, however, was found very oppressive; as it required inquisitorial visits, and affected the lowest of the people. This and all the other assessed taxes were so irregularly levied, that, notwithstanding the discontent excited by them, they did little more than cover the expenses of collection. For this reason, by a motion of the chancellor of the exchequer, they were entirely remitted. In the two years to 1st November, 1657, the revenue amounted to 137,558*l*. In 1719, it amounted, for a year and nine months, to 805,015*l*., and continued to increase; but the expenditure increased in a greater proportion, so that, in 1715, it became necessary to have recourse to borrowing. This was at first to the extent of only 50,000*l*.: in 1731, the debt had risen to 300,000*l*.; in 1763, it was still only 521,000*l*., nor did even the American war raise it higher than 3,186,000*l*. The revenue after this period was greatly increased; in 1789 amounting to 956,000*l*., and on the 25th March, 1800, having risen to 2,684,000*l*. The debt also at this last date was 25,662,000*l*. At the union, the stipulation was made that Ireland should pay two seventeenthths of the whole expenditure of the empire. Under the circumstances which have since occurred, this arrangement has led to a continual increase both of debt and revenue. In 1811, the former amounted to 77,382,000*l*., and the latter to 3,906,900*l*. In 1830, the gross receipt was 4,298,154*l*., the net receipt (deducting drawbacks, &c.) was 4,229,776*l*. The charges of collection, however, were 603,690*l*., which with other payments reduced the net payments into the exchequer to 3,515,296*l*.*

2165. *The particulars of this revenue were:—*

Customs	-	-	-	£ 1,579,183	Post Office	-	-	-	£ 247,712
Excise	-	-	-	1,973,867	Fees, &c.	-	-	-	9,096
Stamps	-	-	-	488,296					

The following were the leading articles:—

Ashes	-	-	-	£ 6,540	Coals	} From Britain	-	-	-	£ 58,661
Auctions	-	-	-	10,883	Salt		-	-	-	43,184
Barilla	-	-	-	13,746	Spirits		-	-	-	6,853
Cocoa and coffee	-	-	-	18,500	Leather	-	-	-	-	28,381
Hemp	-	-	-	5,949	Malt	-	-	-	-	273,852
Bar iron	-	-	-	3,294	Paper	-	-	-	-	21,936
Glass	-	-	-	18,421	Licences	-	-	-	-	112,309
Hides	-	-	-	25,524	Quit-rents, &c.	-	-	-	-	81,056
Pepper	-	-	-	13,570	Deeds and law proceedings	-	-	-	-	128,848
Salt	-	-	-	12,411	Bills and receipts	-	-	-	-	77,539
Seeds	-	-	-	13,936	Newspapers	-	-	-	-	29,047
Foreign spirits	-	-	-	7,500	Advertisements	-	-	-	-	16,337
Home-made spirits	-	-	-	1,481,206	Insurances	-	-	-	-	20,819
Sugar	-	-	-	418,704	Legacies	-	-	-	-	24,270
Tea	-	-	-	445,271	Game certificates	-	-	-	-	12,010
Tobacco	-	-	-	750,500	Law fund	-	-	-	-	45,867
Wine	-	-	-	185,158	Chancery fund	-	-	-	-	14,278
Wood	-	-	-	144,700						

In the last finance account the heads of customs not being distinguished from those of Great Britain, the above are those of the preceding year.

The debt on the 5th January, 1831, amounted to 32,131,424*l*., the charge on which was 1,142,017*l*.; and towards its extinction there was a sinking fund of 183,000*l*.

2166. *The expense of collecting the Irish revenue is very large: in 1824 it amounted to sixteen per cent. on the produce; the rate being, on the Customs, 19*l*. 17*s*.; on the Excise, 11*l*. 6*s*. 11*d*.; on Stamps, 7*l*. 4*s*.; and on the Post Office, 49*l*. 12*s*. per cent. As most strict investigation, however, has now taken place, the boards have been incorporated with those of England, and a variety of changes and reductions have been effected. The expense of collecting the Customs has thus been reduced, in 1830, to 17*l*. 2*s*.; the Excise, to 10*l*. 7*s*.; the Stamps to 5*l*. 14*s*.; and the Post Office to 40*l*. 6*s*. per cent.*

2167. *For local and patriotic objects in Ireland, very considerable sums are allowed out of the public revenue Of these, for the year 1832, there appear the following:—*

Schools and Education	-	-	-	£ 30,000	Female Orphan House	-	-	-	£ 1,833
Protestant Charity Schools	-	-	-	3,000	Roman Catholic College	-	-	-	8,928
Foundling Hospital	-	-	-	26,314	Royal Dublin Society	-	-	-	5,900
Four other Hospitals	-	-	-	10,045	Belfast Academical Institution	-	-	-	1,500
House of Industry	-	-	-	21,192	Nonconforming and other Ministers	-	-	-	24,224
Richmond Lunatic Asylum	-	-	-	1,388	Public Works	-	-	-	33,564
Hibernian Marine Society	-	-	-	950	Dunmore Harbour	-	-	-	7,500

SECT. V. Productive Industry.

2168. *Ireland, in this respect, has long presented a painful spectacle; a great proportion of her people being involved in extreme and squalid poverty. The Irish do not want enterprise, or even industry; but various causes have combined to degrade them in the scale of improvement. Among these we are mortified to state, that the conduct*

long held by Britain must be considered as prominent. Mr. Newenham has given a sad catalogue of the measures taken to suppress the rising industry of the sister country. In 1698, on a petition of parliament, King William was pleased to say: — "Gentlemen, I will do all in my power to discourage the woollen manufacture of Ireland." Accordingly, after several milder expedients had proved ineffectual, it was absolutely prohibited, under the penalty of 500*l.*, and forfeiture of the ship and cargo, to export woollens to foreign countries. Similar measures were taken with regard to glass, hops, and every branch in respect to which any rivalry was apprehended. There was one article, however, the production of a large surplus of which could by no means be avoided. This was black cattle and sheep; but the value of these was effectually cut down by the prohibition to import them into England, the only accessible market. Under these regulations, all the exertions of Ireland to better her condition were cramped, and while Britain was making the most rapid advances, Ireland continued in the same state of depression. However, in consequence of her spirited efforts at the end of the American war, and of the embarrassments of the British government, the most odious and pernicious of these restrictions were repealed. Further advantages were obtained at the time of the Union; and at present, when just and liberal principles on this subject have gained a full ascendancy, every exertion is making to place the two countries in a state of perfect reciprocity. The consequence has been, that in the course of forty years, Ireland has made a rapid progress in industry and commerce; yet some of her greatest evils are so deeply seated, that they have scarcely yet begun to give way to the influence of a more auspicious system.

2169. *Agriculture*, that primary art, has been long in a backward and very depressed state. The farms were, for the most part, small, managed by the farmer himself and his family, destitute of capital, with wretched implements, and with a pertinacious adherence to all the obsolete practices of a rude age. The plough was generally of the most imperfect construction; the mould-board straight, the coulter blunt; in its movement it raised continual obstructions to itself, to remove which required the incessant labour of the ploughman and of one or even two assistants. It is mentioned as the mark of a peculiarly inartificial state of things, that all over Ireland there was only one description of plough, while in England a great variety had been invented to suit the different species of soil. Four horses or bullocks were employed in some districts; but the animals were of deficient strength. The best soils exhausted a great portion of their strength in throwing up weeds, which no effective measures were taken to extirpate. The system also of infield and outfield was strictly adhered to, the ground being heavily cropped as long as it would yield any thing, and afterwards of necessity allowed two or three years to recruit. Although these defects still exist to a considerable extent, yet in all parts of the country, but particularly in the east and north, improved practices and implements are beginning to be introduced. The only obstacles, in fact, to the rapid improvement of Irish agriculture, are the disturbed state of the country, and the habits, so general amongst the occupiers of land, of subdividing their farms into minute portions. But there is reason to hope that the foundations of good order have been laid; and the landlords seem at length to have opened their eyes to the destructive consequences of the continued subdivision of the land, and are exerting themselves to counteract the practice.

2170. *The Irish tenures* are long, some of them perpetual, in which case they may be considered as property, the rent being a mere trifle; a lease of thirty-one years and three lives is very common. These long leases are attended with scarcely any of the benefits which might be naturally expected. As the farmer commences usually without any capital, trusting for the payment of the first year's rent to the produce of his farm, he almost always falls more or less into arrear, and thus lies at the mercy of his landlord. This would be less pernicious, were it the landlord himself with whom he had to deal; but the landlords of Ireland, holding usually properties of immense extent, and being mostly resident out of the country, cannot or will not undertake the task of dealing with this impoverished multitude of small tenants. They devolve it upon the intermediate agents and *middlemen*. The latter, a class peculiar to Ireland, take a large extent of ground, which they let out in small portions to the real cultivator. They grant leases, indeed; but as the tenant, from the circumstances above mentioned, soon comes under their power, they and the agents treat him with the greatest harshness, exact personal services, presents, bribes; and draw from the land as much as they possibly can, without the least regard to its permanent welfare. This system, while it crushes the tenant, is not less injurious to the landlord, into whose coffers there often passes less than one half of the sum paid by the tenant. The only use to which the latter turns his long lease is to divide and subdivide the lands among his children, till the share of each affords only the most miserable aliment, and an overgrown population is fixed upon the farm. An attempt to let land on a different footing can only be effected by the ejection of more than half its existing occupants, who in that case are apt to fly to violent and revengeful courses, so that even a partial endeavour to introduce such improvements has been a main cause of the existing disturbed state. Another injurious mode is that of partnership leases, in which a number of persons take a farm jointly, and make it

a sort of common property. Each is allowed to put upon it a certain number of *collops*; the collop consisting of one horse, two cows, or twelve goats. A degrading stipulation is often introduced into leases, by which the occupant is bound to work for his landlord either without wages, or at a rate lower than ordinary.

2171. *Tithe* is one of the evils of which the Irish cultivator most grievously complains. Although it must in all cases fall ultimately on the landlord, yet to take from the cabin of the peasant the pig which he has reared, or the handful of potatoes which he has raised for the support of his family, is an act peculiarly discouraging and irritating. The exemption of grass lands tends also to discourage tillage. Measures were taken by parliament to promote the commutation of tithes, and were attended with considerable success; and by a late act arrangements are made by which this change must speedily be effected; when the church rates, instead of being taken out of the farmer's produce, will be paid by the landlord out of his rent.

2172. *The extent of country, and the objects of culture in Ireland*, vary considerably from those of the sister kingdom. Its superficial extent is computed at 12,000,000 Irish, or 19,278,760 English acres. Of this, notwithstanding the considerable amount to be deducted for mountain, lakes, and bogs, Mr. Young calculates that there is a greater proportion of productive land than in England. The soil of Ireland is shallow, consisting most generally of a thin sprinkling of earth over a rocky ground; but the copious moisture wafted from the sea, by which it is every where surrounded, produces a quick and rapid vegetation, and in particular a brilliancy of verdure, not equalled perhaps in any other region of Europe. Such a country is of course highly favourable to pasturage; and as this pursuit is suited to the imperfect stages of culture, the rearing of live stock has been long the main staple of Irish husbandry. Its luxuriant plains are depastured by vast herds of black cattle; and from this source is derived the very large quantity of salted provisions shipped from the southern ports. The number of oxen and cows annually killed for this purpose was reckoned at 18,000. This trade has considerably decreased since the peace; but the export of live cattle is extensively carried on. Great facilities have been lately afforded for it by the steam packets. The dairy is also a great branch of industry in Ireland. None of its cheeses, indeed, have acquired a reputation; but butter of excellent quality is made and largely exported. Another species of live stock is an essential article in the economy of an Irish cultivator. The pig usually shares his cabin, and is fed, like himself, on potatoes. It is too great a luxury to be killed for his own consumption; but is sold, and driven to the ports to be salted for exportation. Sheep are bred extensively on the mountain tracts, which are unfit for rearing any other stock. In many places they are bred for the wool and milk. In this last respect, however, goats are more productive; and they are reared in immense quantities in the mountain districts in the north. The Irish know little of the powerful draught horses of England, and do not esteem them equal to their own breed, which is small, hardy, and capable of doing much work upon little food. Poultry are fed in great numbers in and round all the cabins, the interior of which they are admitted to share; a practice extremely favourable to their increase. Great quantities of geese are kept for the sake of the feathers, which are cruelly plucked from the animals alive. The produce of grain is also large, notwithstanding the imperfect processes employed in cultivating it. Wheat and barley were little raised till of late, when both the culture and export of the former have been greatly extended. Still the main objects are oats and potatoes; the former as the subject of a large export, the latter as the staple food of a considerable body of the people. The Irish boast of the potato, as if it were nowhere else produced in equal perfection. Compared with grain of any kind, it certainly affords the means of supporting a greater population upon a given extent of ground. The scope, however, which it affords for the multiplication of the people in miserable circumstances, is generally considered by the political economist as one of the causes of the present distress in Ireland. Flax is also a valuable product of Irish husbandry, affording the material of the linen manufacture. According to a return made to the trustees in 1809, the extent sown was 76,749 acres; in addition to which, the various little scattered patches raise the number probably to about 100,000 acres, supposed to produce at an average about 30 stones per acre; which, at 10s. 6d. per stone, would make the entire value about 1,500,000*l*.

2173. *There is a want of trees in Ireland*. The immense forests which some centuries ago covered a great proportion of its surface, have fallen, and been converted in a great measure into moss or bog. The first step to improvement in a country is the clearing away of its primeval forests; but in this instance, as in many others, the error was committed of sweeping them away entirely. The peasantry were accused of a propensity to steal the timber, which gave occasion to a very severe law, making it penal for any individual to have a stick in his possession for which he could not account. Trees are chiefly found around the mansions of the great proprietors; but, as many of these reside abroad, too little attention has been paid to the rearing of wood as an ornament.

2174. *The bogs of Ireland present an extensive obstacle to cultivation*. They are estimated

by the parliamentary commissioners at 2,330,000 English acres. From them, indeed, fuel is supplied to many districts which would otherwise be destitute of that accommodation; and many have no other timber than that which is dug entire out of the mosses: yet the draining of a large portion would be certainly desirable; and the commissioners seem to think that, from their generally elevated position, this might be done with great facility and advantage. They estimate that 36,000 acres of the Bog of Allen might be drained for 147,000*l*. Mr. Wakefield seems somewhat sceptical upon this point, and observes that, the vegetable substance of the English fens being entirely decomposed, the moment a fen is drained it yields the most luxuriant crops; but that of the Irish mosses, being in an elevated position, retains its component parts in a great measure unchanged, and could with greater difficulty be converted into soil. The great quantity of water beneath these bogs causes often a singular phenomenon, that of moving bogs. Bursting the surface, the bog inundates the surrounding lands, spreading desolation and barrenness through its whole course, which in one instance extended no less than twenty miles.

2175. *In respect to manufactures*, the state of Ireland cannot be described as flourishing; a misfortune for which it has appeared that she may justly accuse the oppressive policy of England. One species of fabric, however, she has been allowed and even encouraged to cultivate, and it has attained to a very considerable magnitude.

2176. *The linen manufacture was first introduced by the Earl of Strafford*, who brought flax-seed from Holland, and workmen from France and the Netherlands. He expended 30,000*l*. of his private fortune in this patriotic object. His attainder, and the subsequent troubles, suspended the undertaking; but it was revived by the Duke of Ormond, who established near Dublin a colony from Brussels, Jersey, and Rochelle; gave lands on advantageous terms to those willing to embark in the business; and, though he had to struggle against indolence and inveterate prejudice, had the satisfaction to leave it in a promising state. After the Revolution, the English parliament, as linen was not supposed to interfere with any branch of English industry, created a board for its promotion; they also, in conformity with the spirit of the times, granted bounties both on the raising of flax and the export of linen. These exertions have met with great success; and the manufacture has become general throughout Ireland, and particularly in Ulster. The following, according to a late parliamentary report, was the reputed value of brown or unbleached linens sold in the markets of Ireland in the year 1824:—

Ulster	-	-	-	-	£2,109,309
Leinster	-	-	-	-	192,888
Munster	-	-	-	-	110,421
Connaught	-	-	-	-	168,090
Total	-	-	-	-	£2,580,708

2177. *The mode of conducting this manufacture* is, however, in several respects, very rude and imperfect. It is generally practised by individuals holding little spots of ground, the culture of which they combine with that of weaving. The same person, or at least the same family, in many cases raises the flax, dresses it, spins it into yarn, and weaves it into cloth. There is too much anxiety to obtain the greatest possible quantity of yarn out of a given quantity of flax, without regard to the quality; and the sorting of the yarn, so that it may be of an uniform texture, suited to the kind of linen intended to be woven, is almost wholly neglected. In some instances, however, it is worked to a most extraordinary degree of fineness. Anne M'Quillin, in the county of Down, could spin 105 hanks to the pound, which would reach 214 English miles. Exertions have lately been made to introduce mill-spinning, which, it is supposed, would generally improve the quality of the yarn, though it could not produce it of such extreme fineness as some of that spun by the hand. Twenty years ago the mill could not produce above fifteen cuts to a pound; now it can make nearly fifty.

2178. *The export of linen from Ireland*, in the year 1824, amounted in all to 49,491,037 yards, of which 46,466,950 were to Great Britain; and 3,024,087 to foreign parts. The real value of the whole was 2,412,858*l*. Of that sent to Great Britain, 31,314,533 yards were retained for home consumption; the rest were re-exported to the same quarters as Scotch linen. This great manufacture is chiefly supported by its own growth of flax. Ireland, however, imports 25,000 tons of hemp from abroad, and 3300 from Britain; also about 7500 tons and 1000 tons of linen yarn; of all which materials the value falls short of 45,000*l*.

2179. *Distillation* is another branch of industry characteristic of Ireland, but by no means attended with the same happy effects. It has hitherto been carried on chiefly in defiance of the revenue and government, and has given birth to a vast system of contraband, equally destructive of morals and of public order. All the mountains, bogs, and deep valleys of the north and west abound with illicit stills, in spots where the most diligent search can scarcely discover them; and where detected, they can scarcely be seized without the aid of an armed force. When the troops are seen advancing, concerted signals are made, and the small light stills are soon conveyed to a distant quarter. The farmers and proprietors encourage illicit distillation as the most ready mode of affording a market for their grain.

The quality of the spirit was long much superior to that produced by the legal distillers, owing to the injudicious restrictions imposed on the latter; so that, in selling, it was considered the highest possible recommendation to give assurance that it "never paid duty." Even in the regular distilleries established in the great cities, Mr. Wakefield gives reason to think that, through a purchased collusion on the part of the officers, not more than half the produce paid duty. He calculates the entire loss on them to be 856,000*l.*, and that on the illicit distillation nearly as much; so that, instead of a revenue of 2,280,000*l.*, which ought to have entered into the treasury, the amount was only 664,000*l.* The most rigorous laws were enacted in vain, for they only rendered the people concerned in this practice more desperate and determined. Of late, however, the system has been entirely new-modelled; the duty, as in Scotland, has been reduced to 2*s.* a gallon, and free exportation permitted; and the strictest measures have been taken to put a stop to abuses in the collection of the revenue. The effect has been remarkable; the quantity of spirits paying duty, which from 1818 to 1822 varied from 3,000,000 to 4,000,000, rose in 1824 to 7,800,000, and in 1832 to 8,657,000; thus warranting a presumption, that the contraband fabrication of this article has been greatly diminished; yet doubts may be entertained if the cheapness of a commodity of which the excess is so pernicious be on the whole beneficial to the country.

2180. *The killing and salting of beef and pork for sale* forms a great branch of Irish commerce. During the American war, the number of oxen and cows slaughtered amounted to about 50,000 annually; but Mr. Wakefield supposes them reduced in 1808 to about 18,000; partly owing to the extended tillage, and partly to the great increase in the export of live cattle. Each animal is found to produce upwards of six cwt. of beef, seven stones of tallow, and nearly one cwt. of hide. The despatch with which the animals are slaughtered, the meat cut up and salted, and afterwards packed, is astonishing. The beef is packed in three different forms, called planter's beef, India beef, and common beef; the first two, having the coarse pieces taken out, and charged 4*s.* additional per cwt. While the export of salt beef has diminished, that of pork has of late been much extended.

2181. *The cotton manufacture*, since 1822, has spread through Ireland in a very surprising manner, particularly in the counties of Antrim, Down, Louth, and part of Dublin. The coarser linen fabrics are disappearing before it, and proceeding to the westward and southward, retaining still an equal hold of the kingdom in general. More recently this fabric has rather declined, and linen has regained the ascendancy.

2182. *The other manufactures* are not of primary importance. A great quantity of wool is, indeed, worked up by the peasantry into frieze, linseys, and flannels, for their domestic use; but the only fabrics on a great scale, which are those of broadcloth at Carrick-on-Shannon, and of flannels at Kilkenny, are on the decline. Breweries have been established in the principal towns, and are rather in a flourishing state. Notwithstanding the great surplus of hides, the want of bark and of skill prevents tanning from being carried to any great extent, and they are chiefly exported raw.

2183. *In the distribution of minerals*, Ireland has by no means been neglected; but some unpropitious circumstances have prevented any of them from being turned to great account. Of these impediments the most material is the want of a sufficient supply of good coal. The most extensive depository is that of Kilkenny, which extends also into Queen's County; but, besides the great expense of working, the sulphureous quality and carbonic acid gas evolved during ignition render it both disagreeable and unwholesome; and it is used for fuel only by the peasantry. It is fitted, however, for the use of blacksmiths and maltsters. The principal work is at Castle-Comer, where about 40,000 tons are annually raised. The coal of Leitrim has absorbed a large capital, but does not promise to be very productive. The fuel of Ireland is in general either coal imported from England and Scotland, or the turf dug out of its immense bogs; but the latter has not yet been found applicable to the fusion of metals. From these causes the veins of iron ore, which are very extensively diffused through the island, have not yet been turned to any important use. The copper, also of fine quality, which is found in the counties of Wicklow and Cork, must be sent over to Swansea to be smelted. The lead, however, of Wicklow is worked to a considerable extent with imported coal.

2184. *Fishery* is a branch of industry for which the extended shores and deep bays of Ireland would be peculiarly adapted. Nor do the inland waters, the rivers and lakes, less abound in the species of fish appropriate to them. The diligence of the Irish in taking fish for immediate consumption is considerable, being urged on by the frequent abstinence from other food which their Catholic profession enjoins. Their trout and salmon are distinguished both for size and taste: the salmon are caught by weirs, stake-nets, and other contrivances, but with so little precaution that their number has been sensibly diminished. The eels also are delicate, and attain a great size; and the use of eel-weirs, a practice but partially known on this side of the Channel, is very general. These processes, however, do considerable injury by flooding the adjoining lands. Dublin, and the other great towns,

obtain a regular supply of sea-fish, though at prices so high as to place the consumption beyond the reach of the lower orders. The curing of fish has made very little progress, when compared with the opportunities which the coasts of Ireland afford. In 1809, Parliament appointed a Board of Commissioners for the promotion of Irish fisheries, placing at their disposal a sum of 5000*l.* to be employed in erecting small piers, fitting out commodious boats, and providing other facilities. Since that time, the curing of fish has made considerable progress, though Ireland still cannot come into any sort of competition with Scotland. In 1824, the herrings produced by the coast fishery amounted to 34,201, on which was allowed a bounty of 6726*l.* The open sea fishery produced 7638 barrels, on which a bounty was given of 17,300*l.* There were also cured 2934 cwt. cod, 2645 cwt. ling, 9500 cwt. hake. The last is chiefly caught on the coasts of Waterford and Cork. There is supposed to be a most extensive bank, extending from its western coast as far as Newfoundland.

2185. *Commerce.* — With the exception of the linen manufacture, which has never been in a sound or healthy state, and which is now far surpassed by that of Scotland, the manufactured products of Ireland are quite inconsiderable. She has, however, very great facilities for the production of raw materials; and it is in all respects more suitable for her, as well as for England, that she should direct her efforts to this department, and import manufactured articles from Britain, than that she should attempt to enter into an unequal competition with the latter in manufacturing industry. Previously to 1806, there were several restrictions on the importation of corn from Ireland into England; but these were wholly abolished, and since that epoch her exports of corn to this country have increased from less than 400,000 to above 2,600,000 quarters! In 1825 the other restraints on the intercourse between Ireland and Great Britain were mostly abolished; and owing to this circumstance, and to the establishment of a regular intercourse by steam packets between Liverpool, Glasgow, Bristol, and the principal towns on the east and south coasts of Ireland, the trade between the two countries has been vastly increased. This has been productive of much advantage to both parties, but principally to Ireland; and, notwithstanding the agitation of which she is the prey, it is not to be doubted that she has made very considerable advances in the way of improvement within the last half dozen years. Owing to the trade between the two countries being now placed on the footing of a coasting trade, no account has been kept, later than 1825, of the reciprocal imports and exports of each, except in the case of corn. The following table gives, however, a sufficiently clear idea of the nature, extent, and progress of this great internal trade.

TRADE OF IRELAND.

2186. Imports into Ireland. — (From *Papers published by Board of Trade, Part I.*)

Value exported to <i>Great Britain</i> -	£ 3,352,069	4,201,078	4,367,425	5,164,483	5,569,465	7,067,252	8,404,289

From the cause above stated, the subsequent accounts have been very imperfect. In 1829, the imports from foreign parts were valued at 1,669,406*l.*; in 1831, they were 1,552,228*l.*; in 1832, they were 1,348,828*l.* The exports in 1831 were 608,938*l.*; in 1832, they were 452,775*l.* Within the last few years there has been a most extraordinary increase in the quantity of grain and live stock imported from Ireland into Great Britain. The former, on an average of 1830 and 1831, amounted to 543,618 quarters of wheat, and 1,563,593 quarters of oats and oatmeal. In 1832, there were imported into Liverpool alone, 338,649 quarters of wheat, value 948,217*l.*; 325,720 quarters of oats, 309,434*l.*; 14,486 quarters of barley, 24,626*l.*; 69,624 cows, 765,864*l.*; 149,090 pigs, 484,542*l.*; 74,260 sheep, 129,955*l.*; 24,077 lambs, 24,077*l.*; 169,817 loads of meal, 203,780*l.*; 177,252 sacks of flour, 407,679*l.*; 10,771 bales of bacon, 64,626*l.*; 292,830 firkins, 15,861 half firkins, and 10,348 coolies of butter, 819,141*l.* These, with some minor articles, made up a value of 4,444,500*l.* The imports into London, Bristol, and other ports, may be presumed to be as much more, and perhaps the whole may not fall short of 10,000,000*l.* sterling.

2188. *The following table* exhibits the relative foreign commerce of the principal ports of Ireland in the year 1824. We add the ships and tonnage belonging to and the amount of customs on each, which a recent report enables us to bring down to 1829:—

Entered at	British.			Foreign.			Ships.	Tonnage.	Customs.
	Ships.	Tons.	Men.	Ships.	Tons.	Men.			
Belfast - - - - -	100	19,123	1090	66	11,992	621	247	25,000	259,000

2189. *The shipping interest* of Ireland is on a very small scale when compared with that of the sister island. On the 31st December, 1830, she had 1424 vessels; the tonnage of which was 101,820, navigated by 7794 men and boys. In 1832 there were built twenty-five ships, of 1909 tons. There were entered inwards, in 1831, 14,499 ships, of 1,420,382 tons; outwards, 9801 ships, 1,073,545 tons. Of this were employed in trade with Great Britain, 13,584 ships, and 1,262,221 tons, inwards; 9029 ships, 921,128 tons, outwards; in foreign trade, 915 ships, 158,161 tons, inwards; 772 ships, 152,417 tons outwards.

2190. *Canals*, so instrumental to the prosperity of England, have been undertaken in Ireland on a bold and extensive scale, but with only a small portion of the expected benefit. This seems partly owing to the excessive magnitude of the plans, and partly to the prevalence of jobbing. Mr. Young says, in 1779, "a history of public works in Ireland would be a history of jobs;" and the observation seems to continue applicable to the 3,000,000*l.* which have since been expended in this manner. The two chief undertakings are the Grand and the Royal canals, both proceeding from Dublin into the interior. The former, commenced in 1756, has, by large advances from government, been completed, at an expense of upwards of 2,000,000*l.* It is carried across

Kildare and King's County to the Shannon, which it joins near Clonfert, about sixty miles above Limerick. This distance is eighty-seven miles, which with a branch to the Barrow at Athy, one westward to Ballinasloe, and several others, makes an entire length of 156 miles. It is forty feet wide at the surface, and has six feet of water. In 1831, commodities were conveyed to and from Dublin, to the amount of 237,809 tons, yielding 36,735*l.* of tolls; which, with somewhat above 10,000*l.* for passengers, afforded a very inadequate return. The Royal Canal, of nearly the same dimensions, reaches from Dublin through the counties of Meath and Longford, nearly eighty-three miles to Tarmonbarry, on the Shannon, about forty miles above the junction of the other canal. The expense was 1,420,000*l.*, while the tolls, in 1831, amounted only to 12,700*l.*, on 130,000 tons, a sum insufficient to defray the annual expenses. The other Irish canals are small and of little importance.

2191. *The roads of Ireland* are and have long been excellent. They are not supported in general by tolls, and those which are so appeared to Mr. Young by no means the best. Any person may present a memorial to the grand jury of the county, showing the necessity of a new road, and if this presentment be approved, the work immediately proceeds. Government have established mail coaches to all the principal towns, and since the rebellion have made fine military roads into the interior of Wicklow; but stage coaches and other means of conveyance, though daily increasing in number, are still indifferent.

SECT. VI. *Civil and Social State.*

2192. *The population of Ireland*, from its great amount and rapid increase, is considered as one of the chief causes of the severe poverty which presses upon the body of the people. Till the census of 1821, the data upon which it was calculated appear to have been somewhat conjectural. In 1672, Sir William Petty, who had been employed on a survey of the country, estimated it at 1,100,000. Mr. Dobbs, between 1712 and 1726, upon a calculation from the number of houses, at six to a house, represented it as varying from 2,000,000 to 2,300,000. Calculations founded on the produce of the hearth duty gave, in 1754, 2,372,000; in 1785, 2,845,000; and in 1788, 4,040,040. In 1812, a census was instituted, but could not, from various obstacles, be made complete; however, by calculating what was deficient, it was estimated at 5,937,000. In 1821, a more complete and effective census gave 6,801,000. That of 1831 amounted to 7,767,401, of whom 3,794,880 are male, and 3,972,521 female.

2193. *The Irish character* presents very marked features, many of which are amiable, and even admirable. They are brave; hospitable to such a degree, that in some counties the door is regularly kept open during meals. "Hospitality is an universal trait, and exists in the north as well as in the south; in the mountain and in the dale." It is much enhanced by the scantiness of the portion which is thus liberally shared with the passing stranger. The Irish are lively, merry, and witty; and even the lowest ranks have a courteous and polite address. They are celebrated for warmth of heart, and for strong attachments of kindred and friendship, which leads them, out of their scanty means, to support their aged relations with the purest kindness. Benevolence is a distinguishing feature of the higher ranks. They are curious, intelligent, and eager for information. With so many good qualities, it were too much to expect that there should not be some faults. They are deficient in cleanliness; have little taste for conveniences or luxuries; and are destitute of that sober and steady spirit of enterprise which distinguishes the English. The love of fighting seems a rooted infirmity. Among all nations not wholly civilised, this is, indeed, a favourite mode of terminating differences; but the Irish may be said to surpass every other people in the extreme promptitude with which they resort to it. Fighting appears their native element, into which they plunge whenever their spirits are roused. It would seem, indeed, to have been formerly almost a regular termination of the social board. The fairs, which, in every town and village of Ireland, are regular and of long duration, afford the grand theatres, first of unbounded mirth, and ultimately of bloody conflict. The Irish do not fight single-handed, but in bands, and on a great scale. On receiving a supposed injury, they go round to their companions, friends, and townsmen, and collect a multitude, with which they make a joint attack on the objects of their wrath. It need scarcely be added, that they show no reluctance to engage in schemes of general and national conflict; and it is remarked that, when these are in contemplation, there is a pause of casual and private battle. The other blemishes of the Irish are rather frailties than sins. They are represented as vain, talkative, prompt to speak as well as act without deliberation: this disposition, with their thoughtless gaiety, betrays them into that peculiar blunder called a *bull*, which their neighbours have so long held forth as a national characteristic.

2194. *The ecclesiastical state of Ireland* is well known as having been one of the chief causes of its unsettled condition. The native Irish did not share in any degree the reformation so unanimously adopted in England and Scotland. When, therefore, the English church was introduced as the established religion, it threw out, as dissenters, the bulk of the Irish population. Even of the protestant part, a large proportion, introduced as colonists from Scotland, were attached to the presbyterian form. The discussions as to the relative number of each seem to be set at rest by the official statements in the Lords' report of June, 1825. It there appears that, of the 6,801,000 which constituted, in 1821, the entire population, 4,980,000 were catholic, and 1,769,000 protestant; of which last there were 1,135,000 belonging to the established church; 577,000 presbyterians (with the exception of about 10,000, all in Ulster); 57,000 of other denominations, chiefly in the same province. The proportion of Protestants to Catholics is, in Ulster, as 1 to 1; in Leinster, as 1 to 4½; in Munster, as 1 to 9½; in Connaught, as 1 to 7½: over all Ireland, as 1 to 2½.

2195. *The Roman Catholic clergy* receive no stipend from government, but are entirely supported by their flocks. They are formed, however, into a regular hierarchy, at the head of which are four archbishops; Armagh (the primate), Tuam, Cashel, and Dublin. Under them are twenty-two bishops, with a vicar-general, dean, and archdeacon in each diocese. The number of catholic priests has been stated at 1400, besides several hundred friars. Their income arises less from any fixed allowance, than from dues, offerings, and presents; and the bishops, to make up their incomes, receive from the parish priests a portion of what they have collected. Mr. Wakefield has attempted an estimate, according to which, Christmas and Easter offerings amount to 337,000*l.*; marriages produce, in licences, fees, and collections, 78,500*l.*; christenings, 12,500*l.*; burials, 12,500*l.*; in all, 440,500*l.* According to Archbishop Curteis, the income of a bishop is about 500*l.* a year; that of a priest varies from 100*l.* to 400*l.* Although a *congé* is asked from the pope, the real election to vacant places rests with the clergy themselves; but as their incomes depend entirely on the favour of their hearers, they are subject to a necessity of choosing popular priests, which is not felt by the established catholic churches. Hence the influence of the priests, always so remarkable under the catholic system, exists in Ireland to an extent perhaps unequalled. On the other hand, many, especially among the bishops, are remarked for their exemplary life, and for the diligent discharge of their functions. They are even sometimes instrumental in preventing riot, in discovering theft, and procuring restitution. The recent admission of Roman catholics to all political privileges, though it does not make any change in the condition of the clergy, has been hailed by the body in general with peculiar satisfaction. It is hoped that it will either make them more friendly to the established government, or diminish their influence in estranging from it the minds of the people.

2196. *The Presbyterians*, as already observed, are nearly confined to Ulster, where they are the most numerous sect. The synod of Ulster is formed into a sort of establishment, consisting of 201 congregations, besides which there are 110 congregations in communion with the Scottish seceders. The ministers receive a royal gift of 14,000*l.* annually, which affords from 50*l.* to 100*l.* to each. The Presbyterians form the most industrious, thriving, and intelligent portion of the people; yet a great proportion have imbibed republican ideas, and they emigrate to America more readily than any other class.

2197. *The Established Church* of Ireland is in union with that of England, and every way similar. It consists of four archbishoprics and twenty-eight bishoprics; but by an act recently passed, two archbishoprics are to be converted into bishoprics; and ten bishoprics are to be abolished. The entire revenue of the Irish church has been ascertained not to exceed 130,000*l.* for the bishoprics, and 602,200*l.* for other benefices. The lands belonging to the bishops are of far greater value; but, in consequence of being let on old leases renewed from time to time on payment of fines, and never coming to a termination, the rent derived from them was greatly under the real value. It is proposed now to offer these leases to the present incumbent, in perpetuity, on payment of six years' purchase of their estimated value, which, it is calculated, will produce about 3,000,000*l.* A tax, moreover, varying, according to the amount of income, from five to fifteen per cent., is to be laid on all livings above 200*l.*; and its produce to be applied to the augmentation of the poorer livings, and the building of glebe houses and of new churches. Hence the parochial tax, called the vestry cess, or church rate, amounting to about 90,000*l.* a year, is no longer to be levied.

2198. *The literature* of Ireland, in modern times, cannot boast any very distinguished pre-eminence; yet she has maintained her station in the literary world. In wit and eloquence, indeed, she has excelled both the sister kingdoms. In the former quality, Swift and Sheridan shine unrivalled; and in the latter, Burke, Grattan, and Curran have displayed daring and brilliant flights. In her graver pursuits, Ireland has not been so happy; though Usher attained the first eminence in theological learning, and Berkeley was the author of a highly ingenious system of philosophy.

2199. *The Irish establishments for education* are scarcely adequate to the magnitude of the country. There is only one university, that of Dublin, founded by Elizabeth on the model of those of England, but not on so great a scale. Of it and of other Irish literary institutions, an account will be found under the head of Dublin. As the constitution of this university is strictly protestant, and does not allow the teaching of catholic theology, the students of that faith must have been all educated abroad, had not government endowed for their use the College of Maynooth. It is supported by a revenue of about 9000*l.* a year, and contains a president, vice-president, and eleven professors, all with moderate appointments. The students receive board and education; and the whole annual expense of each is not supposed to exceed 20*l.* The students of the north resort chiefly to Glasgow for theology, and to Edinburgh for medicine; though there has been an attempt to obviate this necessity by the formation of an institution at Belfast.

2200. *The education of the poor in Ireland* is a subject which excites the deepest interest in all the friends of that country. It appears that, by the 8th of Henry VIII., every clergyman, on his induction, becomes bound to keep or cause to be kept an English school. This act, however, is either obsolete, or so far evaded that only 23,000 children are now

taught in these parochial schools. The greatest effort at Irish education, however, is that made by the Charter Schools, instituted in 1733, which by parliamentary grants and private benefactions have enjoyed an income of 30,000*l.* a year. But this sum, which might almost furnish schools to the half of Ireland, is spent upon 2000 boys, who receive board as well as instruction. Although the act recites no other object than instruction in the English tongue, proselytism has become almost the sole aim. The Hibernian Society, the Baptist Society, and that for discountenancing vice, support schools to a very considerable extent. The Kildare Street Society, founded in 1812, founded numerous schools, in which they endeavoured to induce the Catholics to attend by renouncing all attempts to gain proselytes; but from the entire Scriptures being read in these schools, and other alleged causes, the Catholics were supposed to view them with jealousy. The allowance made to this society was, therefore, withdrawn, and a new plan instituted, in which the moral and literary is separated from the religious education, and is communicated to the youth of both religions during four or five days of the week, while, in the remaining period, religious instruction is expected to be administered by the clergy of the respective churches. Extracts only from the Scripture, approved by the leading catholic clergy, are read in the common school. Local funds, to a certain extent, are required to be contributed. Although this system has met with many opponents, yet, in the beginning of 1833 there had been established under it between 500 and 600 schools, calculated for the education of about 90,000 scholars. In 1824, the number of schools in Ireland was 11,823, and scholars 560,549. Of these scholars 394,742 paid for their own instruction, and among this number were 307,000 Catholics, who thus showed no small ardour in obtaining the benefits of knowledge.

2201. *The fine arts* do not appear to have attained any great excellence in Ireland. Her best painters have sought for patronage in the British metropolis; and the attempts to establish an annual exhibition in Dublin have not succeeded. The Irish harp and native Irish melodies enjoy considerable reputation. The ecclesiastical structures have not that splendour and richness which so strongly mark many of those in England; but the modern edifices, especially in Dublin, display a taste as well as magnificence which render that capital almost pre-eminent.

2202. *In funerals, marriages, and similar solemnities*, the Irish retain several old national customs. The practice of hired howling women at funerals, called *ululates*, is very prevalent; a considerable sum is paid to those employed, though, in cases of necessity, they howl gratis. A still more unfortunate custom is that of the wakes, where thirty or forty neighbours assemble, are entertained with meat and drink, and indulge in every sort of *fun*. Marriages in many parts of the country are marked by some real, or at least apparent, violence; the bridegroom collects a large party of friends, seizes and carries off the seemingly reluctant bride. Alluding to this custom, her going to her husband's house, even in ordinary cases, is called the "hauling home." This is not prompted by any peculiar shyness on the part of the fair sex; on the contrary, the mothers, with whom the affair chiefly rests, display even a feverish anxiety that their offspring should not remain long in a state of single blessedness. The fair sex are treated among the higher ranks with a gay and romantic gallantry; among the lower almost as slaves, being subjected to the most degrading labour. Notwithstanding this circumstance, and although improvident marriages are general among all ranks, while those of affection are deemed by Mr. Wakefield to be very uncommon, Irish wives are said to be extremely faithful; and the sex, amid all its frankness, to maintain a character for chastity.

2203. *Amusement* forms a copious element in the existence of an Irishman. Ample scope is afforded to the Catholics by their numerous holidays, in which diversion and devotion are considered as quite consistent; and the Protestants, however contrary their views in other respects may be, vie with them in this particular. The fairs afford a grand and unlicensed theatre for fun of every description. The chief bodily exercise is hurling, which consists in driving a ball to opposite goals, the same known in Scotland by the name of *shinny* or *shinty*. To this amusement they add horse-racing, cock-fighting, cudgelling, leaping, and dancing; to say nothing of drinking and fighting. Their conversation also affords them much amusement; it is distinguished by loud mirth, seasoned often with a good deal of humour, by singing, and telling long stories. Thus employed, even the poor will often sit up to a late hour.

2204. *The houses of the Irish*, if we except those of the rich, or in towns, which are formed after the English model, are such that hovels, cabins, the humblest terms which can be applied to human habitation, are appropriate to them. They are formed of earth, taken out of the ground on which they stand; whence the floor is reduced at least a foot below the outer level, and becomes a receptacle for all the superfluous moisture. This is the more incommodious as it has no boards, and the bed no frame; nor is the latter raised from the ground, being merely straw spread upon the floor. This humble mansion is shared by all the living creatures, whether with four legs or two, which the family are able to muster; cows, pigs, geese, and fowls: these it is rarely deemed needful to separate by any partition from the other tenants.

2205. *No compulsory provision exists in Ireland for the support of the poor*; a circumstance to which we are inclined to ascribe much of their distressed state, as well as of the backward state of the country in general. Not being obliged to contribute any thing to their support, the landlords and occupiers, have, generally speaking, manifested great indifference to the condition of the peasantry. Few among them have hesitated to allow their estates to be subdivided into minute portions to advance their political interests, or to obtain an increase of rent. But it is abundantly certain that they would have paused before venturing on such a course of proceeding had they been made responsible, in all time to come, for the paupers they were thus introducing upon their properties. The question as to the institution of a compulsory provision is now freely agitated. That it is attended with difficulties no one can doubt. On the whole, however, we are firmly convinced it would be attended by the best effects; and we hope that it may speedily be established.

2206. *The dress of the Irish peasantry* consists chiefly of the native wool, worked rudely up into frieze or linsey; for they seldom can afford to wear the fine linen which they fabricate. But the most prominent feature of this attire among the lowest class, is its lamentable deficiency; in many instances it covers little more than half of the person, and, being defaced by rueful and unseemly gaps, presents an image of extreme poverty. When this deficiency does not exist, the Irishman loves to display the extent of his wardrobe; when going to a fair, he puts on all the coats he has, though the season be midsummer.

2207. *The food of the Irish peasant* is no less scanty than his dress and habitation. It is almost wholly comprised in the potato, without any other vegetable (for he is a stranger to the luxury of a garden), and only in favourable circumstances is it accompanied with milk. As this food, however, according to the observation

long ago made by Smith, is sufficient to preserve him in full health and vigour, the lamentations over it have, perhaps, been carried too far. In the north, the use of oatmeal in the form of cakes and pottage has been derived from Scotland.

SECT. VII. Local Geography.

2208. *Ireland is divided into four great provinces, or rather regions: Leinster in the east, Munster in the south, Connaught in the west, and Ulster in the north. This is independent of the minuter English division into counties, a number of which are comprised in each of the four provinces. These last, indeed, when Ireland was ruled by native governments, formed separate kingdoms. They are still distinguished by marked boundaries, by a different aspect of nature, and by a considerable variation of manners and customs.*

2209. The following Table exhibits the leading provincial statistics of Ireland. The population statements differ considerably from those hitherto published; but they have been obligingly furnished to us by Mr. Porter, of the Board of Trade, as the result of the latest and most accurate digest of the returns for 1831.

Provinces and Counties.	Square Miles.	Improved Acres.	Unimproved Acres.	Estimated Annual Value.	Houses 1821.	Population, 1831.	Cities and Towns, with their Population.

SUBSECT. I. Leinster.

2210. *Leinster* is the richest and most cultivated of the four great divisions, and, as containing the capital and the seat of government, the most important theatre of political events. Though the surface be level to a great extent, it is by no means destitute of considerable and important ranges of mountains. These include almost the whole county of Wicklow, whose bold and picturesque summits are seen even from Dublin. In the interior, the long range of Slieve-Bloom stretches towards the borders of Munster. A considerable part also of the midland counties is covered by the great bog, which crosses the whole centre of Ireland.

After all deductions, however, there remains a large extent of level land, fit either for tillage or pasturage, and employed with some diligence in both these modes of production. This is the part of Ireland where wheat is grown to the greatest extent, oats being elsewhere almost the only grain; and its rich pastures abundantly supply the capital both with cattle and the products of the dairy. Leinster is not a manufacturing region, having the national staple of linen only in some of its northern borders, though that of cotton has been lately introduced from England to a considerable extent.

2211. *Leinster is divided into the counties of* Dublin, Kildare, King's County, Queen's County, Wicklow, Carlow, Kilkenny, Wexford, Meath, Westmeath, Longford, and Louth.

2212. *The county of Dublin is not indebted for its importance to any superiority of soil and climate. It is in general cold, moist, and marshy; and, unless where stimulated by the immediate vicinity of the capital, its agriculture has no claim to pre-eminence, and the condition of the peasantry is not superior to that of their brethren in other counties. It owes its distinction almost exclusively to its containing the capital of Ireland.*

2213. *The city of Dublin presents an aspect scarcely indicative of the ills under which the nation labours. It disputes with Edinburgh and Bath the reputation of being the most beautiful city in the empire. If the brick of which the houses are built impair the effect of the general range of its streets and squares, its public buildings, composed of stone, surpass in grandeur and taste those of any of its rivals. There is no period of Irish record in which Dublin was not an important place. It is mentioned by Ptolemy under the name of Eblana. The Danes, in the ninth century, made it their capital, and enclosed it with a wall about a mile in length, the course of which may still be traced. As soon as the English began to establish themselves in Ireland, its proximity and convenient approach induced them to make it their head-quarters; it grew with the improvement of Ireland and the extension of the English sway. Henry III. granted a charter to Dublin; its privileges were enlarged by successive monarchs; and George II. placed the corporation on its present footing. All its splendour has arisen within the last sixty or seventy years. The numerous streets and squares formed during that period have been built on a regular plan, and contain several superb mansions, which once belonged to the principal nobles. The squares are particularly admired; that of St. Stephen's Green is nearly seven furlongs in circuit; and even the want of regularity in the form and size of the fine houses that surround it, heightens the picturesque effect. Merrion Square, which contains the splendid mansion of Leinster House; Rutland Square, in the interior of which are the gardens of the Lying-in Hospital; and Mountjoy Square, are also spacious and finely laid out. Of the streets, the finest is Sackville Street, 170 feet wide, and adorned with many splendid mansions. To the west, farther up the river, is the old town, originally much inferior to the streets above described, and now bearing marks of decay. Still farther west is the tract called "the Liberty," as being out of the jurisdiction of the magistrates. It is inhabited only by the lowest orders, and exhibits scenes of filth and wretchedness not to be paralleled in any city of the sister island. A room fifteen feet square is frequently let to three or four families; and one house was ascertained to have lodged 108 persons. It is complained that Dublin has been "shorn of its beams" since the Union; when the nobles and gentry, no longer called to attend parliament, transferred their town residence to the more splendid metropolis of the empire. Their Dublin mansions have been converted to humbler purposes: that of the Duke of Leinster, the most splendid of all, is occupied by the Royal Dublin Society; the Powerscourt mansion is now the Stamp Office; that of the Earl of Aldborough is a school; and the house where the parliament held its sittings has been altered for the accommodation of the national bank.*

Dublin, however, can never be deprived of the public buildings, which form its chief ornament. Among

these, indeed, its ancient structures do not stand foremost. The Castle, the residence of the lord lieutenant, is extensive; but its architectural beauty is almost confined to a modern Gothic chapel, erected from the design of Mr. Johnstone, an eminent architect. The cathedral of St. Patrick (*fig. 213.*), and Christ Church have a venerable aspect; but they can rank only secondary to those fine specimens of the Gothic found in the metropolis and other large cities of England: they seem even eclipsed by Mr. Johnstone's modern edifice of St. George's church. The splendid structure, formerly the parliament-house of Ireland, and now the national bank (*fig. 214.*), was built between 1729 and 1739, from a design of Cussels; but an eastern front was added in 1785, from a design of Gandon; and a western front, from one of Parke, shortly after: the whole costing 95,000*l.* The portico is 147 feet in length, supported by very lofty Ionic columns; the whole covering an acre and a half

ST. PATRICK'S CATHEDRAL, DUBLIN.

of ground. The directors of the bank purchased it for 40,000*l.*; and have since, under Mr. Johnstone's directions, expended a considerable sum in alterations and additions. The Royal Exchange (*fig. 215.*), situated almost in the highest part of the city, was built by the merchants, assisted with 13,000*l.* from government. It forms a square of 100 feet, and its principal front has a richly decorated portico of six Corinthian columns.

As the business transacted there, however, is, seemingly without any very good reason, limited to the purchase

BANK OF IRELAND, DUBLIN.

portico, the pillars composing which are the highest in the metropolis: it is of Portland stone, while the main structure is of fine mountain granite. At no great distance, in the centre of Sackville Street, is the

EXCHANGE, DUBLIN.

monument erected to Nelson; an object by no means ornamental. The inns of court, the theatre, the half-finished Roman catholic metropolitan chapel, and several other churches and chapels, with many of the hospitals, may be mentioned as adding to the architectural splendour of Dublin. The citizens display rather a peculiar zeal in forwarding patriotic and benevolent objects. All the usual associations for the relief of distress are supported on a liberal scale. The Incorporated Society for Charter Schools, and the Kildare Street Society for general education, have both their central boards in this city. The Bible and Missionary societies are chiefly branches of those in London. Great zeal is shown in favour of all institutions for the promotion of knowledge. Trinity College was founded in 1593; and its students, who, thirty years ago, did not

FOUR COURTS, DUBLIN.

exceed 500, now amount to 1600. There are seven senior and eighteen junior fellowships, which are said to be bestowed after very strict examination; and the livings in the gift of the university, which are considerable in number and value, are offered to the fellows in the order of seniority. The general constitution seems to be on the English model; though the fellows are less numerous, and the lecturing is more frequent. There are gradations of rank, indicated by a different dress and table; which, though they accommodate in some sense the poorer students, seem contrary to the genuine academic principle. The library contains 100,000 volumes; but its other collections are not equal to those of the Dublin Society. Usher, Swift, Berkeley, Chandler, Leland, Parnell, Burke, Grattan, Curran, with other distinguished characters, are mentioned as pupils of this seminary. The buildings of the College are on a large scale, divided into three quadrangles, for the accommodation of the fellows and pupils. The front towards College Green extends 300 feet, and is adorned with columns of the Corinthian order. The library forms a fourth quadrangle, built of hewn stone, with a rich entablature; and the principal room, 210 feet long and 41 feet broad, is elegantly and conveniently fitted up. At a short distance from town is a well laid out botanic garden. The Royal Dublin Society, incorporated in 1749, for the promotion of husbandry and the useful arts, have enlarged their sphere by a most extensive botanic garden; by purchasing and extending the Leckean museum of natural history; by instituting a school of drawing, with models; and by appointing teachers in all these departments. The Royal Irish Academy, incorporated in 1782, have published many estimable volumes of Transactions. The Dublin Institution has been formed on the model of that of London, and a city library established, on which 8000*l.* has been expended. Although a great literary spirit prevails in Dublin, there are few books printed there, and the art of printing is in a backward state. The works of Irish authors issue from the London presses.

2214. *Dublin, unlike London, has very little foreign trade; but she has a considerable trade with England, particularly with Liverpool. The bay is spacious, and has good anchorage; but the entrance is beset with formidable sand-banks, particularly those called the North and South Bulls, threatening continually to encroach on the channel of the river, which is, strictly speaking, the harbour. It is a still more serious evil that these banks cannot be passed by large vessels at low water; so that vessels embayed at that time of the tide, and attacked by strong easterly gales, can scarcely escape being driven upon one of them; and many have consequently perished. To avert these evils, works have been undertaken, the magnitude of which is scarcely paralleled in the United Kingdom or any part of the world. After having in vain endeavoured to form a bulwark of frames and piles, which could not be kept in repair without constant expense, a double wall has been constructed three miles in length, composed of enormous blocks of granite, dovetailed into each other, the interval filled with gravel; and a light-house erected at the end. Another pier, also of great extent, has been built at Dunleary, now Kingstown, on the opposite or southern side of the bay, which is in progress of being connected by a railway with the capital. To these advantages Dublin unites that of being placed at the termination*

of the two principal Irish canals, the Grand Canal on the south, and the Royal Canal on the north, which penetrate by different lines to the Shannon and the interior of Ireland. In 1829, Dublin paid the sum of 660,000*l.* of duty on imported goods, while that paid at all the other ports of Ireland amounted only to 910,000*l.* The environs are celebrated for their beauty. The vast number of villas and villages which cover the adjacent districts, and are rendered conspicuous by the ground sloping down to the bay; the foreground of the Dublin mountains, and the peculiarly picturesque summits of those of Wicklow in the background, render the situation striking and delightful. To the west, Phoenix Park, a royal demesne of several miles in circumference, affords an agreeable promenade, and has lately been adorned with an obelisk, 210 feet high, in honour of the Duke of Wellington.

2215. *The rest of the county of Dublin* contains only villages, and the interior possesses few interesting objects. The shores of the bay, however, stretching toward Wicklow, include many striking sites; and the view from the Hill of Killiney is almost matchless. On this coast Kingston and Blackrock form agreeable bathing-places; and the former, from the great recent improvements, is likely to increase rapidly. On the border of Wicklow the Dublin mountains are rent by a very singular chasm, called the Scalp. An immense granite rock being here riven asunder, its internal structure is disclosed in a manner almost appalling; and the enormous and irregular masses on each side approach each other so closely as to leave only space for a narrow road.

2216. *Wicklow*, though it contains some stripes of fertile territory, is in general composed of bog, forest, and mountain, and contributes little to the wealth of Ireland. It is, however, one of the spots in the three kingdoms most celebrated for picturesque beauty. This

217

POWERSCOURT WATERFALL.

Glenmalure, running along the foot of Lugnaquilla, the loftiest mountain of Wicklow, above 3000 feet high; and still

218

• GLENDALOUGH.

more Glendalough (*fig. 218.*), which is surrounded by a most majestic circuit of mountains, and contains some remarkable ecclesiastical monuments attributed to St. Kevin, a great patron saint of Ireland in the seventh century. One of his disciples had founded at Glendalough a little city, long celebrated as a seat of religion and learning. Only its site can now be traced; but there are distinct remains of seven churches, among which the cathedral and St. Kevin's kitchen are the most entire. They are small and rude; but their high antiquity, and the character of the surrounding scenery, produce a deep and solemn impression. Loughs Dan and Bray, situated in the bosom of the wildest mountains, and enclosed by dark and lofty rocks, present nature under an aspect the most rudely sublime. Wicklow has veins of copper, lead, and even of gold, which was collected in one year to the value of 10,000*l.*; but the vein was soon exhausted. The towns of Wicklow and Arklow, though well built, are

inconsiderable; yet the latter, at the mouth of the Ovoca, has a little trade, and was once the residence of the kings of Ireland. It was the scene of a memorable action in 1798, when the insurgents, above 30,000 strong, were defeated by a small British detachment.

2217. *Wexford*, to the south of Wicklow, is separated from it by a lofty range of mountains; but the interior contains only detached hills, with a great deal of level land, in which agriculture is pursued with greater diligence, and the tenantry are more comfortable, than in most other parts of Ireland. Barley is a prevailing crop. The woodlands also are extensive and valuable. The scenery of the river Slaney and of the bay of Wexford is much admired, though not comparable to that of Wicklow. Wexford is a place of some consequence, with a large harbour, but much obstructed by sand; yet it carries on some traffic. The staple of linen is scarcely known in this county; but some woollens are made both at Wexford and Enniscorthy. New Ross, in the western part of the county, is a populous and flourishing town, situated on the Barrow, which admits of large ships coming up to its quay.

2218. *Kilkenny*, a fine and extensive county, separated from Wexford by the Barrow, is watered not only by that river, but by its large tributaries the Nore and the Suire. These streams carry off the superfluous moisture, and prevent the formation of bog or marsh to any extent. Kilkenny, being chiefly level, or intersected only by hills of moderate height, is composed almost entirely either of arable or fine pasture land. The latter is employed in extensive dairies, but the system of cultivation is still somewhat imperfect. This county exports a coal well suited for kilns and forges, but not for domestic use; and has also black marble of considerable value. Kilkenny, the capital, finely and advantageously situated on the Nore, is partly built of the marble of the surrounding quarries. Its monuments, ecclesiastical and military, prove its ancient importance to have been still greater. The cathedral is one of the finest in Ireland, and the castle, with its remaining gates and bastions, exhibits indications of that strength which enabled it to hold out against Cromwell longer than any other city in Ireland. At present it flourishes by inland trade, and by a manufactory of blankets and other woollens. The foreign trade of the county is carried on by Waterford, at the mouth of the Barrow, which belongs to Munster.

2219. *Carlow*, a small county placed between Kilkenny and Wicklow, is wholly encompassed by mountains, which however enclose a champaign tract of great beauty and fertility, equally fit for tillage and pasture, and producing the best butter in Ireland. It derives great advantage from the Barrow, which flows along its western border. The town of Carlow is a considerable place, distinguished by an abbey and castle, both of great antiquity; but the latter sunk lately under the attempts to repair it. The town has a manufactory of coarse woollens, and carries on a considerable trade down the Barrow. An extensive catholic seminary has lately been founded here.

2220. *Queen's County and King's County* extend north-west from Kilkenny into the interior of Ireland. Though bordered by the range of hills called Slieve-Bloom, their general surface is flat, forming a table land of very moderate elevation. Part of the great chain of bogs crosses these counties, and renders a large proportion of them unproductive, though it supplies them with cheap and abundant fuel. The remaining surface is highly fertile. Queen's County is situated along the heads of the Barrow and the Nore; King's County reaches to the Shannon; and both communicate by canals with Dublin. These counties have, however, few manufactures except distillery, and no trade besides the exportation of their raw produce. The towns are not of much importance; Maryborough, the shire town of Queen's County, is small; and Philipstown, that of King's County, still smaller. The most prominent place is Portarlington, on the borders of the two counties, though chiefly belonging to the first; a well-built place, with good schools, and the residence of a considerable number of gentry. Tullamore, on the great canal, and Birr or Parsonstown, are the most populous and thriving towns in King's County.

2221. *Kildare* forms a long stripe from north to south, separating the two last-mentioned counties from that of Dublin. With the exception of about a sixth part of bog, it forms a plain of the finest arable soil, well cultivated, and whence the capital is chiefly supplied with grain. The Grand and Royal Canals, which both cross its northern border, afford the means of ready conveyance to Dublin. Kildare-town, though presenting a lofty round tower and some other vestiges of past importance, has dwindled into a paltry village. It is only supported by the races held on the curragh of Kildare, an expanse of several thousand acres of the very finest turf. Naas and Athy, both larger towns, and the alternate seat of the assizes, are still not of great magnitude, though the lofty castle of the former bears testimony to the period when it was the residence of the kings of Leinster. In this county is Maynooth, a small town containing the college established by government for the education of the Roman catholics.

2222. *Meath*, a maritime county to the north of that of Dublin, is one of the most favoured of the kingdom in respect to soil. Its pastures are peculiarly rich, and support vast herds of black cattle, which supply the markets of the capital, and are even exported to England. The products of the dairy are abundant, though not of very superior quality. Of late a spirit of tillage has gained ground, and about a third of the county has been brought under cultivation. It is quite a rural district. Trim, where the assizes are held, is only a small town; Navan and Kells are larger, and pleasantly situated. Tara Hill represents the Tamara of Ossian, and has been more recently distinguished by a signal victory which Lords Tara and Fingall gained over a numerous band of rebels.

2223. *Louth*, stretching over a long narrow extent of coast to the north of Meath, though the smallest in area of any Irish county, is one of the first in point of natural and acquired advantages. An active spirit of improvement has brought almost every part of its excellent soil under cultivation. The linen manufacture has made its way from the bordering territory of Ulster; its produce is chiefly in dowlas and sheetings, with some cambric. Louth presents many samples of the earthen mounds called *raths*; and also of more regular fortifications; it was one of the most central points of the English pale. From its productive character, and the extent of the coasts, which include the mouth of the Boyne, its ports enjoy a very considerable trade.

2224. *Louth contains the important towns of Dundalk and Drogheda*. Dundalk, which ranks as capital of the county, is ancient, populous, and flourishing. It was strongly fortified, and has been the theatre of important historical events; but its lofty towers and castles are now demolished, and have given place to more humble and comfortable dwellings. The town consists chiefly of one large and broad street, whence many lanes are seen diverging. It is the only place in Ireland where the cambric manufacture has been introduced, and continues to flourish. Drogheda, at the mouth of the Boyne, was of still greater importance as a military station, being considered one of the keys of Ireland. In the time of the great rebellion of 1641, it stood a long siege against Sir Phelim O'Neil, but was afterwards taken by Cromwell, who punished its resistance by a most barbarous massacre of the garrison. In 1690, two miles above Drogheda, was fought the battle of the Boyne, that memorable field which established the civil and religious liberties of the empire. The fortifications of Drogheda still remain; but, being of obsolete structure, and commanded on several sides, they would make no effectual resistance to modern artillery. The place has now a better distinction from its excellent harbour and extensive commerce in grain brought down the river in considerable quantities for exportation; in return for which, coals and other commodities are imported.

2225. *Westmeath and Longford* occupy the interior from the two counties last described, reaching westward as far as the Shannon. They consist chiefly of a very extensive plain considerably encumbered with lakes, bogs, and morasses, and subject in part to the overflowing of the Shannon, but including tracts of great extent that are extremely fertile, particularly in oats. The northern boundary of Longford is somewhat rugged and mountainous. Athlone, the largest inland town of Ireland, is situated partly in Westmeath and partly in Roscommon. It is memorable for its resistance to General Ginkle in 1691, previous to the battle of Aughrim, and is still considered an important military station. It is divided by the Shannon into two parts united by a bridge. With this exception, these provinces contain only small country towns and large villages. Mullingar,

in Westmeath, is situated on the Royal Canal, and has a considerable trade. Longford, capital of the county of that name, and Granard, are comfortable little towns; a considerable village bears the classic name of Edgeworthstown.

SUBSECT. 2. *Munster.*

2226. *Munster* includes the south and south-west of Ireland, and, though not the most extensive division of the kingdom, is one of those which presents the boldest and most striking features. Most of the great mountain chains of Ireland traverse Munster; among which are conspicuous the Galties and the mountains of Kerry, which encircle Killarney; so that, notwithstanding the almost boundless plains of Limerick and Tipperary, and the level character of a great part of Cork, it may be considered as a mountainous region. It has manufactures, though not on so great a scale as those of the north; and its commerce is very considerable, chiefly in that grand staple of Ireland, the export of salted provisions. The catholic religion prevails, with little intermixture of that of the English church. Munster is divided into larger and less numerous portions than Leinster; its six extensive counties are Tipperary, Waterford, Cork, Kerry, Limerick, and Clare.

2227. *Tipperary* is a large county, of irregular form, extending over almost the whole frontier of Leinster. It is crossed obliquely by a long chain of mountains called variously Slieve-Bloom, the Devil's Bit, and other uncouth names; and on the south it includes part of the Galties. On the north a small portion of the great central bog extends across the county; but one district, along the upper course of the Suire, bears the appellation of the Golden Vale. Tillage has been introduced, but not to any great extent; but both the sheep and horned cattle are of excellent quality. There are manufactures, chiefly for domestic use; and some coal, similar to that of Kilkenny. Clonmel, the county town, is one of the most considerable in the interior of Ireland: it stood a long siege against Cromwell, who after its reduction demolished the very strong walls and castles by which it was defended, and of which only a few vestiges are now left. Clonmel is a well-built town, with four streets crossing each other, and carries on a brisk inland trade. Cashel is a large and handsome city, the seat of an archbishop, to whose residence a considerable library is attached. It was much more important in ancient times, when it was the capital of the kings of Munster, of whose palace some remnants may still be traced. Noble fragments remain of the ancient cathedral, majestically seated on the summit of a precipitous rock. The choir and nave, 210 feet long, are strewn with the mutilated remains of its former rich ornaments. Here was deposited the Lia Fale, or fatal stone, on which the kings of Munster were crowned. The structure is now abandoned to decay, and a modern cathedral of fine Grecian architecture has been substituted. Cashel contains remains of other monastic edifices, of which Hore Abbey, on the same rock with the cathedral, is a magnificent specimen, still almost entire. The country round Cashel and down the river is peculiarly rich, adorned with a great number of fine seats. Carrick, Cahir, Rosecrea, and Nenagh are rather thriving towns, of some extent; but Tipperary itself no longer retains any trace of that importance which must have once enabled it to give name to the county. Near the small hamlet of Holy Cross is the abbey of that name, built in the twelfth century, of black marble, with peculiarly light and elegant decorations.

2228. *Waterford*, reaching from the southern limit of Tipperary to the sea, is a very mountainous county, and only a small portion under cultivation; the chief branch of rural industry is the dairy, and very great quantities of butter are salted for exportation. There is some fine woodland scenery along the banks of its rivers; but the chief importance of the county is derived from Waterford its capital, one of the principal sea-ports of Ireland, and indeed of the empire. Being placed at the confluence of the Barrow and the Suire, the second and third rivers of Ireland, it enjoys a most extensive intercourse with the interior. The quantity of beef, pork, butter, and grain exported to England is immense. In 1831-2, it was valued at 2,065,861*l.*; of which bacon was 547,000*l.*; butter, 538,000*l.*; wheat and flour, 566,000*l.*; oats, 128,000*l.*; live pigs, 117,000*l.* The southern packet communication with England is carried on from Waterford to Milford Haven. Within these few years, seventy vessels have been fitted out for the Newfoundland fishery. Waterford enjoys the benefit of a deep and spacious harbour, and a quay half a mile long, which has been reckoned the finest in Europe. It is an ancient city, regarded as very strong, till taken by Cromwell: its ecclesiastical monuments are of considerable magnitude, and it has an elegant modern cathedral, with other fine public edifices. Twenty miles to the west, on a small bay, is Dungarvan, reckoned the largest fishing town in Ireland; and its antiquity is attested by a castle and several monastic remains. Lismore, on the Blackwater, said to have been once a rich city, is now forlorn and deserted; but its castle, erected by King John, in 1185, on the verge of a perpendicular rock, still presents marks of ancient grandeur, and has been lately repaired by its owner, the Duke of Devonshire.

2229. *Cork*, to the east of Waterford, is the largest county of Ireland: its surface is extremely varied. On the northern border is the lofty range of the Galties, which present many picturesque features, and command extensive and beautiful prospects; its eastern border partakes of the mountainous character of the neighbouring districts of Kerry; and the rocky shores and headlands washed by the waves of the Atlantic, are of an awful and terrific character. About a fifth of the county consists of mountain and bog; the rest is only traversed by hills of moderate elevation, enclosing fertile and often beautiful valleys, especially that along the river and bay. The style of culture is altogether Irish; in small farms, by poor tenants, chiefly by the spade, and potatoes the prevailing crop. The manufactures are not on a very great scale,—consisting of sailcloth, coarse linens and woollens. There are also some very extensive distilleries.

2230. *Cork*, the great southern emporium of Ireland, has a population of 107,000; being, in point of wealth and magnitude, the second city in the island. Its monastic structures, once considerable, have almost entirely disappeared; their materials having, it is supposed, been employed in modern edifices. The great prosperity of Cork is modern, in consequence of the provision trade, of which it has become the chief mart. The river Lee, at its junction with the sea, forms the spacious enclosed bay, called the Cove of Cork, surrounded by highly picturesque scenery, and composing one of the finest harbours in the world. In consequence of this excellence, and of its convenient situation, the West India bound fleets usually touch there, and take in provisions. The export of salted beef and pork has somewhat diminished since the peace; but that of provisions in general, and particularly grain, has been greatly augmented; and Cork, on the whole, is in a very flourishing and prosperous state. A great part of the old town consists of miserable and crowded alleys; but a number of handsome new streets have been built, and several channels branching from the Lee, which flowed through the city, and were in some degree serviceable to trade, but detrimental to the health of the inhabitants, have been filled up. Cork has a literary institution, with the usual appendages of library, lectures, and botanic garden; and it supports the charitable establishments usual in great cities on a liberal scale.

2231. *Other important towns* are contained in this county. Kinsale, on a fine bay at the mouth of the Bandon, was much more frequented than Cork by the early English monarchs, who bestowed on the place extensive privileges, and viewed it as the key of southern Ireland. It has now, however, sunk under the superior importance of its neighbour; its port is comparatively little frequented except as a watering-place; and it is chiefly supported by a fishery. Youghal, at the mouth of the Blackwater, the largest river of the county, has a good harbour, though obstructed by a bar; and carries on some trade and manufacture. Fermoy, farther up the river, has, through the patriotic exertions of one individual, become thriving and prosperous. Mallow contains a mineral spring, which attracts numerous invalids.

2232. *Kerry*, west of Cork, is also an extensive county, but very different in aspect from the rest of Ireland: instead of the usual verdant level, it presents an assemblage of mountains wild, rocky, and desolate. These are interspersed with valleys and narrow plains which might even be subjected to the plough, but are almost wholly employed in pasturage; and Kerry, like other highland districts, has a small breed of cows, which yield plenty of excellent milk. Its coast is broken into several very deep bays, particularly those of Dingle, Kenmare, and Tralee. There are also numerous islands, most of them covered with immense flights of sea-fowl, which the natives take by the usual adventurous practice of descending the precipices by a rope. A considerable quantity of herrings is caught in these bays. Tralee, the county town, could not in this barren region rise to much importance; it exhibits, however, the remains of a very strong castle, once the proud residence of the Earls of Desmond, when, under the title of Palatine, they exercised the real sovereignty over this part of Ireland; a sway which terminated with their attainder under the reign of Elizabeth.

2233. *Killarney and its lakes* form the pride of Kerry, and, indeed, as to scenery, have no rival in Ireland, scarcely in the British islands. Both England and Scotland possess numerous lakes and of varied beauty; the mountains that enclose them, however, have in general been stripped of the ancient forests which once crowned them, and only detached trees and brushwood now grow along their sides. But in Killarney the mountains of Tomies and Glena are covered to a vast height with the most majestic woods; while the arbutus and other shrubs display a bright verdure peculiar to western Ireland. This feature, however, has of late somewhat suffered from the ravages committed by the axe. Killarney presents, at the same time, all the usual accompaniments of precipices, cascades,

LAKES OF KILLARNEY.

of which rises to 3400 feet, the most elevated point in Ireland. On this side also are the mountains of Tomies and Glena, with their immense forests. Near the western bank is

MUCRUSS ABBEY.

surpassing grandeur and beauty. The most striking spot is at the Eagle's Crag (*fig. 221.*), a stupendous and rugged cliff, which bursts suddenly on the view, rising in a pyramidal form from the water. Throughout all the rocks of Killarney, but here most particularly, the effect of echoes is most powerful and striking. The Upper Lake, the least extensive but the most sublime, exhibits all the loftiest mountains under the most imposing point of view. Its shores are winding and varied with numerous islands, whose rocky sides contrast with the brilliant green of the arbutus. The ascent of the highest mountains, Mangerton to the

deep rocky glens, and long ranges of varied summits. There is only one body of water, to which, however, the term *lakes* is usually applied; so completely is it divided into three bays united only by narrow straits, and presenting each a different aspect. The lower lake, immediately adjoining Killarney (*fig. 219.*), forms the main expanse of water, and presents all the features on the greatest scale. On the eastern shore rise the mountains known by the uncouth Irish name of Macgillicuddy's Reeks, the highest of which rises to 3400 feet, the most elevated point in Ireland. On this side also are the mountains of Tomies and Glena, with their immense forests. Near the western bank is Innisfallen, usually reckoned the most beautiful island in Europe. At the most southern point of the lower lake a much smaller bay branches off from it, through channels formed by Dinis Island. This bay, called Turk Lake, is overhung on one side by the precipitous sides of the lofty mountain of that name, and bordered on the other by the long wooded and winding peninsula of Mucruss. The venerable ruin of Mucruss Abbey (*fig. 220.*) adds greatly to the interest of this part of the scenery. From Dinis Island, a long winding channel of more than two miles leads to the Upper Lake. The scenery seen in this passage is of

north, and Gheran Tual, the highest of the *reeks* to the south-east, discloses awful ranges

EAGLE'S CRAIG.

of rugged precipices and of dark and rocky ravines; and their summits command an astonishing view of the mountain glens and rocky shores of Kerry, the expanse of the Atlantic, and the distant plains of Cork and Limerick.

2234. *Limerick*, to the north of Cork and Kerry, is one of the largest and finest counties of Ireland. Its borders include some branches from the high mountains of Kerry and Tipperary; but the main body of the county consists of a vast plain, of peculiar fertility. An alluvial tract, two or three

miles broad, along the Shannon, is quite exuberant. That noble river, now expanded into an estuary or bay sixty miles in length, runs along the whole northern border of Limerick.

2235. *The city of Limerick*, till it was outstripped by Cork, was considered the second in Ireland, and is now the third. Its situation, in the centre of the grand internal navigation of the kingdom, must always secure to it an extensive trade; and, notwithstanding its distance from the sea, the largest vessels can ascend to the harbour. Limerick is one of the great marts for the export of grain and provisions; the value of those shipped from it in 1831, having been estimated at 854,600*l.* It was anciently considered the strongest fortress in Ireland, and has always stood out to the last extremity for the Catholic cause. Ireton, Cromwell's lieutenant, reduced it only after a long siege, aided by a party within the place. In 1690-1, it stood two long sieges, and yielded only upon those advantageous terms called the "capitulation of Limerick." Its capture was considered as closing the contest in support of the Stuarts. At this day, not more than a twelfth part of the population of Limerick is protestant. The spacious monasteries are almost entirely demolished, nor does the city present any monument commensurate with its grandeur or religious character. The streets, as in most ancient towns, especially in fortified cities, are narrow, crowded, and gloomy; but since the fortifications were demolished, half a century ago, they have been carefully widened, and the new streets laid out on quite a different plan. In a large quarter built by Lord Perry, and bearing his name, they are spacious and regular; and the houses, though only of brick, built in the most handsome modern style. The assembly rooms, theatre, and other modern structures, are elegant and commodious.

2236. *Clare county*, to the north and west of Limerick, completes the circuit of Munster. The Shannon, on the south, and the bay of Galway on the north, form it into a species of peninsula: it is a wild, hilly, romantic district, abounding with fine creeks and harbours, but without any commerce to make them important. It has mines of lead, iron and coal, which have not hitherto been turned to any account. More than half the surface consists of mountain, bog, and waste; its hills, however, are depastured by numerous flocks of sheep, the wool of which is of superior quality. The plains immediately on the banks of the Shannon and the Fergus vie in fertility with any in the kingdom. Ennis, the capital, is situated on the banks of the last mentioned river, by which it communicates with the Shannon. It is considerable, though irregularly built; and its abbey, in the purest style of Gothic architecture, is considered the finest in Ireland.

SUBSECT. 3. *Connaught.*

2237. *Connaught* forms a great peninsula, the most westerly part of Ireland, extending from the Shannon to the Atlantic. This division is of all others the most decidedly Irish, having continued unsubdued long after the English kings claimed the proud title of lords of the island. It still contains fewer English inhabitants; the religion is more universally catholic; industry and manufactures have made less progress, and all the imperfect agricultural implements and processes are in more general use. A Connaught man is said to be considered by the other Irish as of a somewhat inferior class. Disturbances, however, have never taken place here to so great an extent as in the more populous districts of Munster and Leinster. Its shores are penetrated by deep and extensive bays, forming some of the finest harbours in the world; but this boon is of little avail to a region which has nothing to export, and no means of paying for what might be imported. These bays, however, may, and it is hoped will, ultimately afford ample opportunities for the herring and other fisheries, which are yet in their infancy. The counties in Connaught,—Galway, Mayo, Sligo, Roscommon, and Leitrim,—are of great extent.

2238. *Galway* is the largest county of Connaught, occupying the whole of its southern shores, bordering partly on the bay of the same name. The coast presents great ranges of steep and lofty cliffs, which, with the waves of the Atlantic dashing against them, present a grand spectacle. The interior contains two extensive lakes, and is much diversified with

hills, though there are few which are not fit at least for pasturage. The cattle are of good quality, and the flocks of sheep, in this as in other parts of Connaught, are more extensive than in other parts of Ireland. The fisheries of herring and salmon are considerable, and, though interrupted by the late disturbed state of the county, are reviving. This region has only a small share of the linen manufacture, and much complaint is made of the imperfect state of all the agricultural processes and implements. Galway, however, has always been a considerable town, and is still supported by some inland and foreign commerce, by a considerable fishery, by the resort of the gentry to it for sea-bathing, and as the only scene of gay society to be found in Connaught. It was once very strongly fortified both by nature and art; and to obtain the protection of the walls, the streets were made narrow, and the houses high, massive, and gloomy; but they have of late been considerably opened, and suburbs built, of a more gay and elegant description.

2239. *Tuam* is an ancient, handsome town, of considerable extent, the seat of an archbishopric. Ballinasloe, on the eastern border, holds the greatest cattle fair in Ireland, where the oxen and sheep of the pastoral counties of Galway and Mayo are mustered for the capital. At the mouth of the bay of Galway are the bold and rocky islands of Arran, inhabited by a hardy race, who seek their food by tilling the rude soil, by fishing, and by descending, fastened to the top by ropes, the precipitous sides of the cliffs, in search of the numerous sea-fowl which there build their nests.

2240. *Mayo* is also a very extensive county, occupying most of the northern coasts of the Connaught peninsula. A great part is elevated and rugged; some of the mountains rising to upwards of 2600 feet; but many of their sides are verdant, and the valleys rich and well watered; so that Mayo is a fine pastoral county. Oats and potatoes are raised for immediate consumption, but chiefly with the spade; or if the plough be used, it is drawn by four horses. The estates are large, but the farms small, and much subdivided; a circumstance which produces the usual effect of great poverty. Mayo contains no town reckoned of sufficient importance to return a member to the imperial parliament. Castlebar, however, the county town, is well built, with a linen hall; and the linen manufacture flourishes, being chiefly indebted to the patriotic exertions of the late Lord Lucan. Killala, a pleasant straggling village, on a bay of the same name, is chiefly noted for the landing effected in 1798 by a body of French troops under General Humbert, who penetrated to Castlebar, defeating a British corps assembled to oppose them; but were finally obliged to surrender to Marquess Cornwallis.

2241. *Sligo* occupies a remaining portion of the Connaught coast, chiefly round a bay of its own name: it contains a considerable quantity of bog; but the remainder consists of a sandy gravelly soil, well adapted to the production of barley and oats; so that pasturage is not so exclusively the employment here as in the two last-mentioned counties. There are a number of lakes, some surrounded by hills, and very picturesque. Salmon is caught in large quantities. The linen manufacture has made considerable progress, and is extending. Sligo, the capital, at the mouth of the river and the head of the bay of the same name, was in early times a considerable place: it has suffered severely in civil contention; yet, by the advantage of a good situation and harbour, it has attained considerable importance and trade. In the vicinity is a remarkable circle of stones, called the Giant's Grave, somewhat resembling Stonehenge.

2242. *Roscommon* is a long inland county, extending from south to north, chiefly enclosed between the Shannon and its tributary the Suck. It is mostly level, presenting only occasional hills, finely watered, and celebrated for its rich pastures; but the increase of population and manufactures has caused a great part of them to be lately brought into tillage; it contains some pretty little lakes, among which Lough Key is particularly admired. Roscommon is ancient, and marked by some ecclesiastical antiquities, but it is not now so important as Boyle, pleasantly situated on a river of the same name, over which there are two fine bridges, and in its neighbourhood are the ruins of a stately abbey, founded in 1512, the arches of which, forty-six feet in height, are deemed models of Gothic architectural grandeur. Elphin, the seat of a very ancient episcopal see, is only a village.

2243. *Leitrim* extends through the interior northward from Roscommon; it is filled with high mountains, presenting nature under bold features, often heightened by the ruined castles which crown their summits. There are extensive veins of iron, lead, copper, and coal, the last of which only has been wrought to some extent; but Mr. Wakefield does not think they will ever supply the wants of Ireland in this particular. There are good pastures in the valleys, and on the sides of the hills; and pretty large quantities of oats are raised. The linen manufacture is extending, and there are some considerable potteries. Carrick on Shannon, which ranks as the county town, and Leitrim, which gives name to it, are both, however, only pleasant villages.

SUBJECT. 4. *Ulster.*

2244. *This fourth part of Ireland* presents in many respects a superior character to the other three. It is not indeed so fertile as Leinster, nor derives, like it, any lustre from being the seat of government; but its population is more industrious, better instructed, and every way in more comfortable circumstances. The presbyterian form of worship, introduced by the Scottish settlers under the reign of James I., is the prevailing one, and has been accompanied with the same beneficial effects as in the country from which it came. The linen manufacture, the staple of the country, has here its chief seat, and is carried on almost in every village. If Ulster has not the numberless bays and fine harbours vainly lavished upon Connaught, those of Belfast, Londonderry, and Lough Swilly are sufficient for the wants of commerce. Its scenery cannot indeed rival the peculiar charms of Killarney; but Lough Erne has high beauties, though of a different character; and the coast of Antrim, in the boldness and peculiar character of its rock scenery, is without a match in any other part of the world. The counties of this province, which are numerous, will be considered in the following order: Fermanagh, Donegal, Londonderry, Antrim, Down, Armagh, Tyrone, Monaghan, Cavan.

2245. *Fermanagh* is a somewhat rough county, comprising a large proportion of mountain and bog, but with fertile valleys, in which, besides the usual products of oats and potatoes, flax is cultivated to the extent of about 5000 acres. It affords the material for the manufacture of linen, which is very generally diffused. The territory contains much more wood than is usual in Ireland. The waters of all the high grounds flow down into Lough Erne, a noble lake, forming the pride of Fermanagh. It extends upwards of twenty miles, being the whole length of the county, and is divided into two parts, connected by a long narrow channel. Both portions are studded with numerous islands, covered with fine woods, which seem to dip into the water; and in sailing through them the lake continually changes its aspect, assuming successively the appearance of a river and of a bay. At other places, long wooded promontories are seen stretching far into the waters; and,

though the immediate borders of the lake are not mountainous, lofty distant eminences form the general background to its prospects. Castle Caldwell, Belturbet, and Belleisle are the spots in which its beauties are peculiarly concentrated. The latter is an island of 200 acres, adorned with every variety of hill, dale, and wood. The chief and almost only town is Enniskillen, delightfully situated on an island in the channel that connects the two lakes. This site, accessible only by two opposite bridges, renders it very defensible, and enabled it to make its noble stand against the army of James II. This led to the formation of the regiment of cavalry celebrated in our military annals by the appellation of the Enniskillen dragoons.

2246. *Donegal* includes a great extent of the north-western coast of Ireland, full of deep bays and fine harbours. In its interior, however, it is the least favoured of the Ulster provinces, and consists almost entirely of mountain, moss, and moor, with only a few productive valleys. It is often called, with some adjoining districts, "the black north of Ireland." It abounds in the bold and rude features of nature. This county is tolerably inhabited and cultivated, considering its natural disadvantages; but distillation on an illicit basis forms too active a branch of its industry. There are great opportunities for fishery; and considerable efforts have been made, with some success, to promote that employment. Lifford, its very small county town, stands on the Foyle, upon the borders of Derry. Ballyshannon, almost at the opposite extremity, is a thriving town, beautifully situated on the channel by which Lough Erne pours its waters into the Atlantic. Raphoe is a celebrated episcopal see, but now only a decayed village. The place bearing the name of Donegal is no longer of any importance.

2247. *Derry, or Londonderry*, is a large and fine county, one of the most northerly in Ireland. It is crossed by a long range of mountains, whose principal peaks are from 1000 to 1500 feet high, and a considerable part of whose surface consists of heath and bog. There are, however, fine valleys, and even extensive plains, which are cultivated with some diligence, but according to that system of minute subdivision which is the bane of Irish agriculture. The linen manufacture flourishes in full vigour, chiefly, according to the Irish system, among the little farmers and cotters, who combine it with the cultivation of a few acres. The county abounds with granite, basalt, freestone, and lime; it has some fine rock crystal, and veins of coal, but they are not worked to any extent. Londonderry is a fine city, situated at the point where the broad river Foyle, after traversing a great part of this county and that of Tyrone, falls into the broad basin of Lough Foyle. It is ancient, being the theatre of remarkable events even in the time of the Danes. In 1608, after the attainder of O'Neale, it was granted by James I. to the citizens of London, whence it derived the first part of its name. But its chief distinction was from the siege sustained by the city in 1690-1, against the united forces of Ireland under James II., when, after being given up by the regular commanders, the defence was taken up and nobly maintained by a clergyman of the established church, of the name of Walker. Londonderry is now a handsome town, composed of four main streets crossing each other at right angles, and surrounded still by its old walls in full repair, serving rather for ornament than defence. It has an ancient Gothic cathedral, and some handsome modern edifices. It is now supported by an extensive commerce, for which Lough Foyle, though its entrance is somewhat impeded by a bar, affords a spacious and secure harbour. Its chief intercourse is with America and the West Indies, to which it exports the linen manufacture in this part of the country. Coleraine is a well-built agreeable town on the Bann, which flows from Lough Neagh, and on which is the most extensive salmon fishery in the island; but the rapidity of the stream obstructs the navigation upwards.

2248. *Antrim*, occupying the north-eastern corner of the kingdom, opposite the coast of Scotland, is one of the most remarkable districts of Ireland, in regard to natural features as well as to commerce and industry. It is not, indeed, peculiarly favourable to agriculture. A great part of the surface is composed of mountains, not very lofty, but rugged, composed chiefly of rock and moss, and even its best soils are scarcely available for agricultural purposes till improved by the use of the lime with which the country abounds. In the interior the mountains have nothing peculiar in form or aspect; but where they face the waves of the ocean, they are broken into vast perpendicular precipices, exhibiting the basaltic columnar form on a grander scale than exists in any other part of the world.

2249. *Of these objects, the Giant's Causeway* (*fig. 222.*) is beyond comparison the most cele-

THE GIANT'S CAUSEWAY.

brated and magnificent. Three natural piers or moles, 400 feet in height, here stretch out into the sea, and are visible above the water for about 300 yards. The walls are composed of dark basaltic columns, of the most regular form, and so closely united, that only the blade of a knife can be thrust between them. Each column is distinct from the others, and divided into jointed portions, as

perfect as if art had formed them; there being in each part a projection, which is lodged in a corresponding concavity or socket of the one contiguous. The coast eastward of the causeway is composed of a succession of capes, presenting the most sublime scenery; dark precipitous cliffs, rising regularly in gradually retiring strata, and formed into various broken colonnades which might suggest the idea of palaces overwhelmed in ruins.

2250. *Other striking features* distinguish the coast of Antrim. Conspicuous above all others is Fairhead, called also Benmore; a promontory which forms nearly the north-eastern point of Ireland. It consists of a vast mass of columnar greenstone, composing a mural precipice, rudely columnar, and 250 feet high. At its feet lies a chaos of huge masses of rock, heaped together in the wildest confusion, and forming a scene of ruin the awful grandeur of which has scarcely a parallel. Against this the sea heaves in a solemn majestic swell, the peculiar attribute of the Atlantic waters. Carrick-a-Rede (*fig. 223.*) is a small island composed of a mass of basalt, imperfectly formed into columns, separated from the continent by a chasm of sixty feet. The fishermen, however, have occasion to resort to it with the view of placing nets to intercept the salmon; to reach it, therefore, they have constructed a daring and singular bridge, formed of two strong parallel cables fixed to each side, with planks inserted between them. This slight pontage is subject to violent movements, and, if not judiciously trodden, may precipitate the passenger into the abyss; but the fishermen, accustomed to tread it, carry great loads across without the slightest appre-

nension. Several of the precipitous cliffs are adorned with the ruins of ancient castles, the

223

CARRICK-A-REE.

no less remarkable as the scenes of busy industry and crowded population.

224

DUNLUCE CASTLE.

grandest of which is Dunluce (*fig. 224.*), whose extensive area covers the long ridge of an almost insulated rock, which presents its perpendicular face to the ocean. The walls enclose the entire surface of the rock, and rise up as a continuation of its precipitous sides. In one place, the rocky base having given way, the apartment above actually overhangs the sea. But leaving these wild and romantic scenes of nature, let us proceed to the towns of Antrim, which are

2251. *Belfast*, the grand emporium of the north of Ireland, has risen to greatness by recent and very rapid steps. It is scarcely mentioned before the beginning of the sixteenth century. It was made a borough in the fifth of James I., when a castle had been built, which gave it some consequence in the subsequent civil wars; but it was burnt in the year 1708. Carrickfergus, by means of peculiar privileges, was then enabled to monopolise all the trade of this part of Ireland,

till these privileges were bought up by the Earl of Strafford. The career of competition was then opened to Belfast, and she gradually outstripped all her rivals. In 1660, the town contained five streets; and, as is supposed, about 6500 inhabitants. At present there are considerably above 100 streets, and the population in 1831 was about 53,000, exclusive of a large suburb in the county of Down. The linen manufacture is very flourishing at Belfast, and that of cotton is rapidly extending; besides which there are various minor fabrics. Commerce, however, is the main source of its wealth. The linen fabrics of the north are largely exported, along with oats, oatmeal, and salted provisions; the entire value of which, in 1810, amounted to 2,900,000*l.* The duties of customs, which in 1801 were 182,314*l.*, had risen in 1829 to 259,000*l.* Belfast Lough forms a noble and secure bay, and though the channel at the mouth of the Lagan was originally rather shallow, it has been so deepened by art that vessels drawing thirteen feet water can come close to the wharfs. Belfast is mostly built of brick; but several public edifices, recently erected, the Commercial Buildings, the Museum, St. George's Church, &c., are handsomely ornamented with pillars of freestone. The bridge over the Lagan, remarkable for its length, is otherwise defective; but a new one is erecting. Belfast has several commercial and literary institutions; and in 1810, the Royal Academical College, a seminary on an extensive scale, was founded.

2252. *The other towns of Antrim* can boast little more than names known in history. Antrim itself has lost its former importance, though beautifully situated near the great body of water called Lough Neagh, which covers about 100,000 English acres, and borders on five counties, — Armagh, Tyrone, Londonderry, Down, and Antrim. Its flat shores possess little of interest or beauty; and its overflowings have converted into bog about 60,000 acres round it. This lake abounds in fish, among which are char, shad, and other rare species. Carrickfergus, at the mouth of Belfast Lough, is a very ancient town, once the emporium and key of northern Ireland. It was here, in particular, that the Scots made their inroads; and in 1316, after a very long and obstinate defence, it was taken by Robert Bruce. In 1689, after all Ireland had embraced the cause of James, Marshal Schomberg landed with a force of 10,000 men, destined to re-establish the English and protestant supremacy. Since that time, Carrickfergus has yielded the palm of commerce entirely to Belfast, and is supported only by being the county town and resorted to as a watering-place. Lisburn is a prosperous town, with a manufacture of damask. Ballycastle is a small town in the north of Antrim, distinguished by the vicinity of coal mines so extensive that it has been supposed they might supply a great part of Ireland, if a safe harbour could be formed at which to ship them; but the dreadful swell which the north-west winds bring in between the continent and the opposite island of Rathfriland baffles such an attempt. Mr. Boyd, the proprietor, obtained 23,000*l.* from government for the erection of a pier; but it was overthrown by the waves, and lies now in ruins. Ballymena, in the heart of the county, is a thriving place, with a good linen market.

2253. *Down* is a fine county, commencing on the south bank of Belfast Lough, and penetrated by several large lakes, as those of Strangford and Carlingford. The last of these receives the Newry, which communicates by a canal with Lough Neagh. The Mourne mountains, on the southern border, exceed 2000 feet in height, and form a conspicuous object; and there are a number of detached hills; but a large extent of the county is level, and a greater proportion is under tillage than pasturage. The combination of farming and weaving exists in a remarkable degree; and the linen fabrics are not only extensive, but some of them very fine. Of late, however, those of cotton have gained a preference in many districts. Down, or Downpatrick, celebrated in tradition as the burial-place of the patron saint, is of moderate dimensions, and its public

buildings respectable. Newry is larger and more flourishing. These advantages are owing to its situation in the bay of Carlingford, and its canal communication with Lough Neagh, which enable it to export the linen manufactures and provisions produced in an extensive district. It is ancient, but has been repeatedly destroyed, and in 1689 was reduced to ashes by Marshal Berwick; so that it is now quite a new town. Donaghadee, a considerable port, with a large substantial quay, is chiefly remarkable for the ferry between it and Portpatrick, the shortest sea communication with Britain, and by which packets are despatched and live stock in very great quantities conveyed over.

2254. *Armagh* immediately in the interior from *Down* is also a fine and agreeable county. A range of high mountains runs through it, but in general it is only pleasingly diversified with little hills, the bogs are no more than requisite for supplying fuel, and only a small part is left unproductive. Both culture and manufacture are prosecuted with great activity. The linens produced in 1824 were reputed at 568,000*l.*, being more than those in any other county, and exceeding a fifth of the produce of the whole kingdom. *Armagh*, the capital, was celebrated in the early history of Ireland as one of its most extensive and populous cities, and has always been the ecclesiastical metropolis of the kingdom. The Augustine monastery, and the college attached to it, ranked for a long time among the most celebrated institutions in Europe for religion and learning; the latter, it is said, could once boast of 7000 students. It sunk, however, under successive ravages by the Danes, the English, and, finally, the Irish insurgents under O'Neale, and not being supported either by foreign commerce or the residence of a government, it fell into great decay; but by good fortune had for its primate Dr. Richard Robinson, to whose munificent exertions is ascribed its revival and its having become one of the prettiest little cities in Ireland. To him *Armagh* is indebted for the repair of its large ancient cathedral, for a library, and an observatory. The linen market is well supported by the flourishing state of the manufacture in *Armagh*. The only other place of consequence is *Lurgan*, near *Lough Neagh*, a very thriving manufacturing town.

2255. *The three counties of Tyrone, Monaghan, and Cavan* occupy a great proportion of the interior of *Ulster*, and present a very uniform aspect; a considerable extent of mountain and bog, fertile plains, rude cultivation, and the linen manufacture. O'Neale, Earl of *Tyrone*, was long one of the most formidable enemies of the English power; but being attainted and vanquished, the title and estates were forfeited, and belong now to the house of *Beresford*. *Omagh* is the county town of *Tyrone*, but is not so considerable as *Dungannon*, a large, populous, and handsome place, once the chief seat of the O'Neales; but this powerful castle was demolished by the parliamentary forces. *Strabane* is also a populous place, finely situated on the *Foyle*. *Monaghan* and *Cavan* are both tolerable county towns, which alone possess any importance in their respective shires.

CHAP. V.

FRANCE.

2256. *France* is a great and powerful kingdom, placed, as it were, in the centre of the civilised world, and for several centuries distinguished by the conspicuous part which it has acted on the theatre of Europe. Its contiguity to Britain, and even the jealousy and enmity which have so long subsisted between these mighty rivals, renders it peculiarly deserving of an attentive survey.

SECT. I. General Outline and Aspect.

2257. *France* is bounded on the north by the Channel, which separates it from England, and by part of the frontier of the Netherlands. On the east it is bounded by Germany, from which it is divided by the Rhine, and by Switzerland and Italy, which lie on the other side of the mighty barrier of the Alps. Its southern limits are the Mediterranean and the broad isthmus filled by the Pyrenees, on the other side of which extends the Spanish peninsula. On the west is the Atlantic, and more especially that vast gulf called the Bay of Biscay. The southern extremity, on the line of the Pyrenees, falls in 42° 4' N. lat., the northern beyond *Dunkirk* in 51° 10', making in length eight and a half degrees of latitude. The breadth may be from 8° 2' E. long., to 4° 4' W. long. making thirteen degrees of longitude. This will give dimensions nearly square of 595 miles from north to south, and 550 from east to west. The superficial extent according to a report presented to the minister of finance by the royal commission appointed to survey the kingdom, is 26,218 square leagues, or about 209,000 square English miles, containing 51,910,062 hectares (about 129,000,000 acres).

2258. *The surface of this very extensive territory* is in general level, although it borders and is encroached upon by the greatest mountain ranges of Europe. The Alps cover the full half of its eastern frontier, and their branches extending into *Dauphiné* and *Provence*, render them very rugged and romantic regions. The Pyrenees, which rank second among the chains of the Continent, range along the southern border, and cover with their branches *Roussillon* and *Gascony*. On the east, where France reaches to the Rhine, are the *Vosges* and other chains of moderate height, parallel to that river. The only range exclusively French, is that of *Auvergne*, in the centre of the kingdom, which not only includes all that province where it rises to the height of 5000 or 6000 feet, but stretches by a winding line along the left bank of the *Allier* to *Languedoc*, parallel to the coast of the Mediterranean, where it is called the *Cevennes*. But by far the greater part of France, including the whole north and the whole east, is one widely extended plain, which yields in very high perfection all the fruits and products of the temperate zone.

2259. *The rivers of France*, though not of the first magnitude, are noble and commodious. Traversing almost every part of the kingdom, they afford ample means of internal navigation; and the broad plains which border on them yield the most luxuriant harvests. The *Loire*,

Alps transmit to it the Isère, and the classical stream of the Durance: its entire length may be 500 miles. The Seine, though of inferior magnitude, claims distinction, as flowing by the metropolis: it rises on the frontier of Burgundy, and runs almost due north till it re-

ceives the parallel and nearly equal Aube, when their united waters flow west and north-west. Before reaching Paris, it receives from the south the Yonne, and from the north, almost under the walls of the capital, its greatest tributary, the Marne. At Paris it is navigable for vessels of considerable burden. Beyond Paris, the Seine makes some extensive windings, and is augmented from the north by the waters of the Oise bringing those of the Aisne. It then passes the fine and flourishing city of Rouen, and, spreading into an estuary, joins the English Channel at the ancient port of Havre. The Garonne has a course of still less extent, though its broad navigable stream, flowing through a magnificent plain, the most productive in valuable wine of any in France, gives it a high commercial importance. It rises near the eastern Pyrenees, and flows northward to Toulouse, where it assumes a steady north-west course, during which, swelled from the north by the Aveyron, the Lot, and the Dordogne, and passing the great haven of Bordeaux, it becomes an estuary, capable of receiving the largest vessels. The Rhine is to France only a liminary river for somewhat above 100 miles; but its great tributaries the Moselle, and the Meuse rise and have most of their early course within its territory. The important Belgic river, the Scheldt, also rises within the French territory.

2260. *France has no lakes which, in a general view, seem worthy of mention.*

SECT. II. *Natural Geography.*

SUBSECT. 1. *Geology.*

2261. *Primitive and transition districts.* In France there are six districts where the older rocks, or those of the primitive and transition classes, prevail: viz. Western Normandy, with Britany and Anjou; the northern side of the Pyrenees; the provinces of the Lower Alps, Upper Alps, and part of the Isère; Central France, or the table-land of France; central part of the Vosges; and the Ardennes.

2262. (1.) *Western Normandy, Britany, and Anjou.* In this region the rocks are partly Neptunian, partly Plutonian; the Neptunian strata are gneiss, mica slate, clay slate, greywacke, quartz rock, and limestone; the Plutonian rocks are granite, syenite, greenstone, and porphyry.

2263. (2.) *Northern side of the Pyrenees.* On the French side of the Pyrenees the central rocks are of primitive formation, and consist of mica slate, clay slate, limestone, or marble; reposing upon these, and forming the great body of the range, are rocks of the transition class; viz. clay slate, greywacke, and transition limestone.

2264. (3.) *Province of the Lower and Upper Alps, and part of Isère.* In this mountainous region there are magnificent displays of many of the more interesting formations of the primitive and transition classes.

2265. (4.) *Central table-land or plateau of France.* The centre of France is occupied by a vast table-land or plateau of old rocks, in general granite, which forms the mountains of Bourgogne, the Limousin, Aveyron, Ardèche, and the Cevennes. It is more than eighty leagues in breadth from the heights of Limoges; but in proceeding towards the south, it gradually thins off, and terminates in a point which connects it with the Montagne Noire. This latter group of old rocks forms a kind of peninsula, which is separated from the Pyrenees, by a longitudinal basin of secondary and tertiary formations. The acclivities of this central granitic table-land, and some of its hollows, are covered more or less densely with newer rocks of various descriptions. Besides these, there occur on its eastern part a splendid display of volcanic rocks. The primitive and transition rocks of this table-land are the following; viz. granite, porphyry, talc slate, serpentine, gneiss, clay slate, greywacke, and limestone.

2266. (5.) *Central part of the Vosges.* The oldest rocks in this range of mountains, and which are said to belong to the transition class, are the following: granite, syenite, hornblende rocks, greenstone, red quartziferous porphyry, augitic porphyry, dolomite, diallage rock, serpentine, talc slate, clay slate, greywacke, with anthracite, granular and compact marble or limestones.

2267. (6.) *Ardennes.* That part of this range of mountains included within the limits of France, which belongs to the older part of the geognostical series, is composed of various clay slates, with greywacke, all of which seem to belong to the transition class.

2268. *Secondary districts.* The lower and flatter parts of France which extend from the primitive and transition districts, are composed of secondary and tertiary deposits, more or less covered with alluvial matters; and in some quarters intermingled with volcanic rocks. The secondary formations are arranged in the same order, and exhibit similar relations with those already described in our account of Britain. The mountain limestone and coal formations form, when contrasted with their abundance in Britain, but a small portion of the surface of France; while the new red sandstones, with the series of the Jura limestone, including the oolites, form great tracts of country. Chalk, or uppermost rock of the secondary series, occurs in vast abundance, forming two basins, the one the northern, extending in length from the northern extremity of Artois to the southern limit of Touraine, and in breadth from Havre de Grace to near Bar le Duc. The northern side of the southern basin extends

from Rochefort to Cahors, and the southern side ranges along the northern face by the Pyrenees.

2269. *Tertiary districts.* France is remarkable on account of the great extent of its tertiary deposits; of these the following may be considered as the principal ones: — 1. That of which Paris forms the central point; which extends towards the north as high as Laon, and southward to Blois; while it stretches across from Pontoise on the west to Epernay on the east. 2. The great southern deposit, which extends from the south side of the river Gironde to the south bank of the river Adour. 3. The south-eastern deposit, which covers part of the provinces of Herault, Gard, Bouches de Rhône, Var, and Vaucluse. 4. The deposit in the valley of the river Allier, and that in the upper part of the course of the Loire. 5. The great deposit in the course of the Rhine and Saône, extending from about Valence to Dijon. 6. The tract along the Rhine, extending from Basle to the neighbourhood of Carlsruhe.

2270. *Volcanic districts.* True volcanic rocks occur in France only in the great central table-land or plateau; in the provinces of Loire, Haut Loire, Cantal, and Puy de Dôme. The volcanic rocks are basalt and basalt tuffa; trachyte with its tuffa; and lava, with its tuffas, scorïæ, &c. The newest of these rocks are the lavas; while the basalt and trachytes appear of more ancient date, although still not very old, as we find them breaking through rocks of the tertiary class.

2271. *Alluvial districts.* Alluvia of every description occur in France. *Diluvium* or the old alluvium forms extensive tracts in many quarters of the kingdom, where it contains remains of extant species of animals, of which the most characteristic are those belonging to the order pachyderma, as the elephant, rhinoceros, &c. Diluvium is also found in caves along with bones of extinct animals, particularly of the carnivorous genera; and rents and fissures in strata are sometimes filled up with a diluvium also containing remains of extinct animals, of which the most characteristic are the small herbivora. Bone caves and bone breccia occur at St. Antonin and St. Julien near Montpellier; at Billargues, Vendargues, and Pezenas-Herault; at Anduze and St. Hippolyte, in Gard; at Aix, in the department of the mouths of the Rhone; at Villefranche and Lauraguais, in the Upper Garonne; and at Perpignan, in the Eastern Pyrenees. This diluvium is covered, to a greater or less depth, with the various well known kinds of modern alluvium and of vegetable soils.

Mines and Quarries.

2272. *Coal mines.* Coal of various descriptions, as glance, bituminous, and brown coal, are mined in the following provinces in France, affording annually but a small return for so vast a country: — Allier, Aveyron, mouths of the Rhone, Calvados, Gard, Herault, Isère, Haut Loire, Loire Inférieure, Mayenne and Loire, Moselle, Nièvre, Nord, Pas de Calais, Puy de Dôme, Haut Rhin, Bas Rhin, Haut Saône, and Tarn.

2273. *Iron mines.* Iron mines, some of them of considerable importance, occur in the following provinces: — Ardennes, Charente, Cher, Côte d'Or, Dordogne, Doubs, Eure, Eure and Loir, Forets, Indre, Indre and Loire, Isère, Jura, Loire Inférieure, Haut Marne, Moselle, Nièvre, Nord, Orne, Ourthe, Haut Rhin, Bas Rhin, Roër, Haut Saône, Saône and Loire, and Vosges.

2274. *Mines of silver and lead.* The principal lead mines and silver mines are the following: —

	Mines of		Quintals of Lead.		Marks of Silver.
Finisterre	-	Poullauen	-	about 8,000	- 1200
Ditto	-	Huelgoet	-	3,000	- 1600
Roër	-	Bleyberg, &c.	-	16,000	- —
Lozère	-	Villefort	-	18,000	- 1500
Isère	-	Vienne	-	1,500	- —

2275. *Copper mines.* These are situated in the following provinces: — High Alps, Rhone, Rhine and Moselle.

2276. *Zinc mines.* Calamine is found in different parts of France, but is only mined in the provinces of Ourthe and Roër.

2277. *Mines of manganese.* This metal is mined at Romanèche and St. Micaud, in the province of the Saône and Loire; at Suquet in Dordogne; in the mountain of Tholey in Moselle; at Laveline, near Saint Dier, in the Vosges; and at Saint Jean de Gardonnenque in the Cevennes.

2278. *Mines of antimony.* Antimony occurs in the provinces of Charente, Haut Loire, La Vendée, Cantal, Allier, Gard, and Puy de Dôme.

2279. *Mines of vitriol and alum.* The principal mines of sulphate of iron or vitriol are those of Saint Julien de Valgargue, near Alais, which furnishes annually 30,000 quintals; and that of Becquet and of Goincourt, near Beauvais, which in some years affords 15,000 quintals; that of Ural, in the province of Aisne, and of Gersdorf, in the province of Bas Rhin. The most considerable alum mines are those on the banks of the Meuse, in the province of Ourthe. There are also celebrated manufactories of alum at Montpellier, and at Javelle near Paris. Some considerable beds of rock salt have been dis-

covered at Vic, in the department of Meurthe. One of these is upwards of fourteen yards thick, and another has not as yet been cut through. Although cobalt, arsenic, nickel, and tin also occur in France, no considerable mines of those minerals have been established.

2280. *Quarries.* The most extensive quarries are those of marble, building-stone, slate, gypsum, millstone, and flint. Different kinds of marble are raised at Givet, Brabançon, Mons, Namur, Boulogne sur Mer, Caen, Troyes, Montbar, Cosne, Tournus, Narbonne, Aix, Marseilles, Tarb, and in many valleys in the Pyrenees. There are quarries of excellent building-stone in the departments of La Manche, Calvados, Moselle, Côte d'Or, Yonne, Oise, Seine, Loire, Dordogne, and in many departments in the south. Vast slate quarries are worked in the provinces of La Manche, Meuse, Ardennes, Maine and Loire, and at the foot of the Pyrenees. In many other places, and particularly in Champagne, &c., there are quarries and pits of clay for brick and tile making. The gypsum of the neighbourhood of Paris, the chalk of the departments of Marne and Seine, the talc named *chalk of Briançon*, the millstone or *buhr-stone* of Ferte sous Jouarre, are objects of considerable commercial importance. The departments of Yonne, Cher, and Lower Charente, supply all France and different foreign nations with gun-flints. *Among the clays met with in France*, that of Forges les Eaux, was formerly in great repute in Holland for the manufacture of pipes; the clay or earth of Belbœuf, near Rouen, is considered an excellent material in the purifying of sugar; and the potters' clay of the vicinity of Beauvois and Montereau, and the porcelain earth or kao-lin of Saint Yriex, near Limoges, are highly esteemed.

SUBJECT. 2. Botany.

2281. *Having devoted already so great a portion* of our space to preliminary remarks upon vegetable geography on its more extended scale, and to that of Great Britain in particular, we must content ourselves with a more limited account of the plants of other countries, otherwise we should greatly overstep the bounds prescribed to us by the nature of the present work. Following the plan here adopted for the arrangement of the different countries, *France* comes next under our notice; and a more interesting field for the geographical botanist does not exist in Europe; not only because of its extent and vast variety of surface, the great height of its mountains, and its geological structure; but because, by the labours of its naturalists, especially Lamarck and De Candolle, the vegetable productions of France have been better explored than those of almost any other country in the world. All that we can do here, however, is to notice in general those that are the most interesting, from their utility, their beauty, or some circumstances connected with their history; or as showing how vegetable forms or groupes are situated, in regard to their distribution, upon the surface of the earth.

2282. *France*, extending, as it does, from lat. $42^{\circ} 8'$ to 51° N., or nearly to the latitude of London, and from 9° east longitude, to 5° west, is bounded by the Mediterranean, and the great chain of the Pyrenees on the south; by the Atlantic on the west; by the British Channel and the Netherlands on the north; and on the east by Savoy, Switzerland, and Germany, which form, for its entire length, a vast mountain barrier. Such an alpine region cannot fail to exert a manifest influence on the vegetation of a country; not only because of its own peculiar productions, depending in part on their elevation, and in part on their soil and geological structure, but by their exposure, even at the same elevation, on two opposite sides; that of the south will be found to exhibit very different vegetable forms from that of the north; and such mountains often exercise a more powerful influence in limiting the surrounding vegetation, than even seas and rivers.

2283. *Lamarck and De Candolle*, in a very interesting Botanical Map which accompanies their *Flore Française*, 3d edit., have divided France into five regions:—

2284. (1.) *The region of maritime plants*, which of course extends every where along the coast, from Ostend to Bayonne on the north and west, and from Perpignan to Oueille on the Mediterranean; together with the *Salines* in the interior of Dieuse and Château Salins near Nancy, and those of Durkheim and Frankensthal near Mayence. Thus we find that a vegetation similar to that of the sea-shore exists in the interior, whenever that interior yields a sufficient quantity of marine salt. All the maritime plants of the north of France, according to M. de Candolle (and they have the greatest affinity with those of England), are equally found in the south; but the reverse does not hold good; for a very large proportion of the French Mediterranean plants of the sea-shore grow very sparingly, if at all, upon the shores of the Ocean, principally indeed on the coast of Gascony, and reach no higher than the mouth of the Loire, or at most to the middle of Britany.

2285. (2.) *The region of mountain and alpine plants.* When the French, by their conquests, included the Pyrenees, the Alps, and Savoy within the range of the floras of their own country, this region constituted the very richest of any flora in Europe; for it included a country, not only of considerable extent, but mountains, and in very southern latitudes, many of whose crests rise greatly beyond the line of perpetual snow. As France is now limited, the mountains of the Vosges near Strasburg, and of the Cevennes, and those of Auvergne, whose origin is volcanic, exhibit its most alpine scenery: among the latter, the Puy de Sasi, one of the Monts d'Or rises to an elevation of 6300 feet above the level of the sea. The

Plomb du Cantal is estimated at 6200, and the Puy de Dôme at 5000 feet. If the summits of the Pyrenees and of the Jura be considered as forming the natural barrier of France, as constituting her line of separation from the adjacent territories, she will still possess an exceedingly rich alpine flora in the northern side of the former and the western side of the latter mountains. But the line of demarcation of this region is nevertheless not so distinctly marked as in the preceding region. The valleys exposed to the sun often participate in the vegetation of the southern provinces, while the cooler valleys exhibit a growth which has more in common with the vast plain in the north and centre of France. However, it is undeniable that these same districts do contain a very considerable number of plants which are peculiar to them, and found on almost all the more elevated mountains of France; for whatever differences the chain of the Vosges and the Jura may present from those of Auvergne, the Cevennes, and the Pyrenees in the south, it is allowed that the aspect of their vegetation offers considerable traits of similarity, and that the greater part of the mountain plants are alike found on the different chains.

2286. (3.) *A third region*, and a very important and interesting one, is that of the *Mediterranean plants*: this, of course, is bounded on the south by the Mediterranean Sea, and stretches inland till you come to the foot of the mountains, or following the course of the Rhone, extending north as far as Montelimart on that river; or it may be said to occupy or constitute the great basin of the mouth of the Rhone.

2287. (4.) *A vast region is occupied by the plains*, whose vegetation is very uniform. This comprises more than one half of France, and especially all the plain country situated to the north of the chains of mountains. Many of these plants are found in other regions already indicated; but it wants the species which are peculiar to each of those respectively.

2288. (5.) and *lastly* — *MM. Lamarck and De Candolle* indicate an intermediate region, which includes plants partaking of the nature of the plains of the north and the provinces of the south. This occupies a large portion of the south-west of France, and some districts up the valley of the Rhone between Montelimart and Lyons.

2289. *The map just alluded to* has these different regions represented in different colours, and is attended with this advantage, that, by the slightest inspection, a general idea is conveyed of the prevailing nature of vegetation in any given district. We see that the plants of the southern provinces resemble more those of the north as you advance by the west side of France than by the east; how that the floras of Mans on the border of Normandy, and of Nantes upon the Loire, in lat. 47° and 48° , scarcely differ from those of Dax and Agen, between lat. 43° and 44° ; whilst on the east side of France, the productions of Dijon and Strasbourg vary considerably from those of Montpellier and Aix, situated at nearly similar relative distances from each other. All this is accounted for on the principles we have already laid down, namely, that the stations of plants are mainly influenced by temperature; and that the mean temperature of a place is greatly determined by distance from the equator, and elevation above the level of the sea. According to M. de Candolle, an altitude of 460 feet above the level of the sea affects the temperature nearly to the same extent as a degree of latitude nearer to the north in our hemisphere.

2290. *By comparing the western provinces of France* with the eastern, we see that the surface of the former is but little raised above the level of the sea; for, even at a considerable distance from the coast, the hills scarcely exceed 300 feet; whilst, on the other hand, upon the western side, in the midst of a mountainous region, the plain has generally an elevation of from 1300 to 1600 feet. This height diminishes, it is true, on the Belgian frontier; but there the temperature is sensibly affected by the second cause adduced, namely, the distance from the equator. Thus, there is nothing but what is conformable to physical laws, in the southern plants having a greater resemblance to those of the north upon the west, than on the east side of France.

2291. *But even where the mean temperature* is the same, the distribution of plants between these two parts of France may yet be very different, on account of the different degrees of temperature at particular seasons of the year. We have already stated that, the latitudes being the same, maritime countries enjoy a more equal temperature than districts removed from the sea; in other words, that the summers are less warm, the winters less cold: thus, the provinces of the west of France, which are all maritime, experience this degree of uniformity; which cannot take place in the east, being far from the sea, and in the vicinity of the mountains.

2292. *Plants now, in what concerns climate*, may be divided into two classes: those which suffer from a severe winter cold, but which, during summer, do not require an excess of heat; and those which can endure great severity of cold in winter, but, during summer, require a great proportion of heat. In the first class, M. de Candolle places all those trees which, without being resinous, preserve their leaves, and consequently their sap, through the winter; in fact, the greater proportion of the trees of the south being found, whether indigenous or naturalised, towards the north in the maritime provinces; such as the Live Oak, the Cork Tree, the Kermes Oak, the Strawberry Tree (*Arbutus*), the Bay, the Fig, the Phillyrea, &c. On the other hand, in the second class, that is to say, among such as can

brave a great degree of cold, and do so because the movement of the sap is interrupted by the fall of the foliage, is the Vine, &c., and those that avoid cold because the plants, or at least their stems, are annual, such as Maize. It may be readily supposed that the individuals belonging to the second class will flourish better, and become more easily naturalised on the east than on the west coast of France.

2293. *Let us apply this law to a peculiarity in regard to the cultivation of those most precious vegetable productions of France, namely, the Olive (fig. 227.), the Maize, and the Vine (fig. 228.).* Mr. Arthur Young, during his travels in France, paid great attention to agri-

228

227

THE OLIVE

THE VINE.

culture and the mode of cultivation adopted there, and published a map of the country, in which he represented, by three nearly parallel lines, the northern limits of the three plants just alluded to, the Olive, the Maize, and the Vine. It excited the surprise of many, that the lines should ascend most to the north on the east side of the country, or, in other words, that the plants in question should grow farther north in the eastern than in the western districts; directly the reverse of what takes place in regard to the aboriginal native productions of the soil. This apparent contradiction is reconciled by the twofold comparison of the physical nature of the east and west of France, and of the character of the plants cultivated, as compared with the wild species.

2294. *The nature of the cultivated productions in question forms a striking feature, which cannot fail to arrest the attention of a traveller while journeying through the districts thus appropriated, and forcibly to exhibit their agricultural riches.* In the extreme south of France, between a line drawn from Narbonne, in lat. 43° N. and in the meridian of Paris, to a little below Grenoble, he will find the plains, parched and dry as they naturally are, rendered still more melancholy by the lurid green of the olive-groves. Between that line and another drawn from the mouth of the Garonne rather below 46° , to near Strasburg, in the north-west, he will observe, together with the vine, which is by no means wanting in all the southern provinces, fields where the gigantic maize (fig. 229.) takes the place of what we usually term bread-corn; again, between it and a line extending from the mouth of the Loire to the Rhine, passing at about an equal distance between the Meuse and the Moselle, he will find, intermingled with vineyards, fertile fields of corn, wheat (fig. 260. *a*), oats (*b*); and barley (*c*), whilst, north of that line, there exists a most perfect similarity in agriculture with that which prevails throughout the greater part of England. Fruit trees of all the kinds that are grown with us, there attain a much greater degree of perfection than in our country, because of the increased heat of the summers.

2295. *Thus, in what concerns a great portion of the territory of France, its vegetable productions much resemble those of the southern parts of Great Britain.*

2296. *It is not, perhaps, generally known that that most useful root, the Potato, was cultivated in almost every part of Europe before its value was appreciated, and its culture*

became general, near the capital of France.

229

THE MAIZE.

To England is due the credit of first growing it upon a large scale. Upon the Continent it was introduced between the years 1714 and 1724 into Swabia, Alsace, and the Palatinate; and in 1730 to the vicinity of Berne. In 1774, potatoes were known on the mountains of the Cevennes, where they now constitute a main portion of the food of the people: but it is principally to the famous M. Parmentier that France owes the general use of potatoes. The following anecdote may give some idea of the assiduity with which this philanthropic individual laboured to generalise their culture: it is well attested that he farmed some spots of ground in the vicinity of Paris for this sole purpose, though the prejudice against potatoes was then so strong, that few of the poor persons to whom he offered the roots would accept of them. However, M. Parmentier soon suspected that people occasionally stole his potatoes to eat them: he was well pleased at this, and continued to plant what he hoped would be purloined, rightly concluding that the experience of the thieves would contribute to diminish the established prejudice. After much trouble and many years, he had succeeded in propagating potatoes in several situations, when the dreadful scarcity, the consequence and effect of the revolutionary disturbances, suddenly rendered their cultivation universal; and now they form so constant an article of food, that the common people generally believe them to be aboriginal natives of the country.

2297. The mountains of France exhibit our alpine plants, with many others that are

230

WHEAT, OATS, AND BARLEY

peculiar to themselves, and which they possess in common with the higher Alps of Switzerland, Savoy, Germany, and the Pyrenees.

2298. Of the intermediate region, as De Candolle terms it, a great portion lying in the south-west of France, embraces a country called the *Landes*, where the shepherd-peasantry, whether walking, or at rest during the day, live upon stilts (*xcangues*, in the language of the country): this custom gives them the opportunity of viewing the land around in search of their sheep, for a great extent, of wading through the numerous shallow lakes of water; and by these means it is said they can traverse triple the space of ground they could do by the ordinary mode of walking; when they stop, they support themselves by a long stick behind. In this same district a vast extent of flat land near the ocean, and extending from Bayonne in the south to the Tête de Buch in the north, and for a distance of from four to twelve leagues inland, is occupied by forests of Pine (*Pinus maritima*) (fig. 231.): these are called *Pignadas*, and they give a remarkable feature to the *Landes*, in conjunction with

the habits of the people and their dress, the latter consisting entirely of sheep-skins

231

THE PINE.

with the hair outwards, little different in outward appearance from the flocks which it is the great object of their lives to tend. The resinous substances of the pine are extracted in immense quantities; in doing which, one man takes care of 3000 trees. The country being so dry, these pignadas are liable to alarming conflagrations; one of them that took place in 1803, continued burning for two months. The mode adopted for extinguishing them is remarkable; when one part of the forest is in flames, it is customary to set fire to another spot, at a greater or less distance, according to the magnitude of the evil; a current of air soon takes place between the burning masses, which drives the conflagration from both sides on the intermediate trees; these are shortly consumed, the fire dies out for want of fuel, and the rest of the forest is preserved.

2299. But the Mediterranean region, which we have already mentioned, and whose vegetation partakes of what is found to characterise the whole shores of that vast inland sea, has many plants so different from those of the rest of France, that it would be unpardonable did we not particularise some of them.

2300. Almost every where in this region, the soil is described as consisting of the secondary limestone of the Jura, extending to the very brink of the sea, forming arid coasts, often utterly destitute of vegetation, or clothed with Wild Olives and the Aleppo Pine (*Pinus halepensis*), with Evergreen Oak, Pistachio-Nut, Myrtles, and numerous species of Cistus. Here too, is found one species of Palm, the *Chamærops humilis* (*Palmetto* or *Dwarf Palm*); but it grows principally in the environs of Nice. At the opposite extremity of the Mediterranean region, namely, about Roussillon and Provence, and there only in the hotter parts, are seen Indian Fig (*Cactus Tuna*), and the American Aloe (*Agave americana*): the introduction of these is due to the Spaniards, who brought them to Europe from the New World. Schouw regards the Mediterranean shores in general as the kingdom of the Caryophyllæ and Labiata; this latter family especially abounds in the south of France, and particularly the genera *Phlomis*, *Teucrium*, *Thymus*, *Lavandula*, and others, remarkable for their aromatic qualities. In the same places, and always on very stony ground, the elegant *Coris monspeliensis* excels the heaths of our own country in beauty. The mulberry is cultivated throughout this territory; and among other useful fruits, the Fig, the Jujube, the Pomegranate, the Date, and the Pistachio, all arrive at great perfection. The Orange can scarcely be said to be cultivated without shelter in any part of France. It is grown, however, and somewhat extensively, at the Isles d'Hières, and in the vicinity of Nice, that happy climate which is probably unequalled by any part of Europe:—

“There summer reigns with one eternal smile,
Succeeding harvests bless the happy soil;
Fair, fertile fields, to whom indulgent Heaven
Has every charm of every season given.
No killing cold deforms the beauteous year;
The springing flowers no coming winter fear;
But, as the parent rose decays and dies,
The infant buds with livelier colours rise,
And with fresh sweets the mother's scent supplies.”

Corn, which is but a secondary article of culture, ripens at a very early period; so much so that it is not unfrequent to carry barley which has been reaped on the coast into the mountains, where the seed is sown, and a second crop is produced the same year. Many plants may be here enumerated which this country possesses in common with Greece and Italy, and even the Spanish peninsula, and which seem to accompany the Olive. Mirbel has drawn up the following list of woody kinds, which inhabit these provinces:—*Pinus Pinaster* and *Pinea*, *Juniperus phœnicea* and *Oxycedrus*, *Quercus Ilex*, *Suber* and *coccifera*, *Celtis australis*, *Ficus Carica*, *Osyris alba*, *Laurus nobilis*, *Fraxinus Ornus*, *Phillyrea latifolia* and *angustifolia*, *Jasminum fruticans*, *Vitex Agnus-castus*, *Nerium Oleander*, *Diospyros Lotos*, *Styrax officinale*, *Arbutus Unedo*, *Viburnum Tinus*, *Tamarix gallica* and *africana*, *Myrtus communis*, *Punica Granatum*, *Philadelphus coronarius*, *Cratægus Azarolus*, *Mespilus pyracantha*, *Ceratonia siliqua*, *Cercis Siliquastrum*, *Rhus Cotinus* and *Coriaria*; *Pistacia Lentiscus*, *Terebinthus*, and *vera*; *Rhamnus Alaternus*, *oleoides*, and *infectoria*; *Zizyphus vulgaris*, *Paliurus australis*, *Capparis spinosa*, *Melia Azedarach*, *Acer monspessulanum*, &c.

2301. *Hitherto the attention of naturalists in the study of vegetable geography has been directed to those plants that grow upon the surface of the earth: Humboldt alone, in his Carte Géographique des Plantes, has indicated the station of some subterranean Fungi, and in a general way has marked the ocean as the habitat of Ulvæ and Fuci (fig. 232).* It

232

ULVÆ AND FUCI.

remained for M. d'Orbigny to describe, to a certain extent at least, the Zones and Bands inhabited by the marine Algæ (Sea-Weeds). This he accomplished upon the coasts in the Gulf of Gascony, and particularly on the shores of La Vendée and the Charente Inférieure, partly by diving to considerable depths in the sea, and partly by means by drag-nets fixed to graduated cords; and the result of his observations are given in the *Mémoires du Muséum d'Histoire Naturelle*, vol. vi. With extracts from this, as we shall scarcely have again the opportunity of touching on this beautiful and interesting tribe of plants, we

shall conclude this sketch, already too much extended, of the vegetable geography of France. Maritime plants, says M. d'Orbigny, grow in the most opposite temperatures: every country, every latitude, and every situation possessing some which are peculiar to itself. Still, climate and temperature appear almost alike to many of these productions, which are found by voyagers in every different ocean, while others require particular spots and climes: some few preferring the mouths of rivers, and the brackish waters of salt marshes, where the bitterness of the sea is modified by the admixture of fresh water, and in such situations attaining to an enormous size, as *Ulva lactuca* var. *altissima*, while to the greater number of these plants, fresh water proves absolutely destructive.

2302. *As for those kinds which grow indifferently every where in the sea, they seem to be increased without any attachment to solid bodies, as Fucus natans, &c. Banks of great extent formed by this plant, are often found within the tropics, of such dimensions as to retard the progress of navigation. Some individuals among these groupes may frequently be seen which bear the appearance of having been originally fixed to rocks, their flattened, disc-like stem yet retaining a portion of such substance. There seems to be ground for the supposition that, though these sea-weeds are capable of living and growing in the water, unattached to any soil, yet that they must primarily spring from some solid body, as no young plants of this kind are ever found between the tropics.*

2303. *Some of the Algæ prefer the southern sides of rocks, others affect an eastern western, or northern exposure; but they change their position according to the difference of latitude: those which are found on the southern side in cold climates, being generally seen on the northern in the warm or temperate regions. Certain species live near the surface, and close to the sea-beach: others, at various degrees of depth: the first would seem to enjoy the regular exposure to light and heat which they experience during the turnings of the tide; the second, on the contrary, shun the influences of the atmosphere; and, growing and fructifying in depths where the light can scarcely ever penetrate, they bear, without receiving any injury, both the enormous column of water which constantly presses upon them, and the severe cold which exists in those regions. There are even parasitical Algæ, which grow indifferently upon all the others, and some which only affect peculiar species.*

2304. *Many sea-weeds* prefer such spots as are exposed to the fury of the waves and the action of the currents, where they are perpetually floating in an agitated medium : others dwell in the hollows of rocks, or in marine gulfs, where the water is generally calm. The lapse of a few days puts a period to the existence of some kinds, whilst the tempests of successive winters fail to destroy others. The general aspect is apt to change in several individuals, so that, were it not for more stable characters, derivable from their fructification, texture, &c. they might be mistaken for novel species.

2305. *A number of the more delicate marine plants* are quickly destroyed by a removal from their native place of growth ; but the greater proportion, being coriaceous, and insoluble in salt-water, live for a length of time in different situations ; and it is not uncommon to find, upon our own shores, the *Algæ* of the most distant regions, which have traversed the ocean, and yet remain unchanged in their general appearance. From these circumstances it becomes a necessary inference, that it is not all the *Algæ* that are found in any country which may be said to belong to that country.

2306. *The proportions of marine plants* are as variable as those of terrestrial ones. Some are barely discoverable with the highest magnifiers ; while others rise from the various depths of the mighty ocean, and, forming at its surface an angle of greater or less acuteness according to the force and velocity of the currents and the tides, then suffer their long summits to float upon the waves, and receive the benign influences of atmospheric light and heat. During the great equinoctial floods, the sea often forsakes, periodically, certain rocks, which are only uncovered at such times. If, during that interval, the sun shines forth, or the north wind blows, many of the minute and delicate *Algæ*, thus exposed, dry up and die ; while others, though equally circumstanced, revive immediately upon the return of the genial fluid.

2307. *A certain proportion of marine plants* are natives of our own seas, while we only owe the accession of many species to the force of the winds, waves, and currents, especially to that which generally goes under the name of *Gulf Stream*, and is called by the French the *Mexican Current*. Almost all the northern *Algæ* grow in the Gulf of Gascony. It is not so with those from the Mediterranean and Southern Ocean ; a very small number of them are there seen in a living state, and their almost northern limit never exceeds the mouth of the Loire, or at farthest the rock of Morbihan. Independently of the influence of temperature, this circumstance may be attributed in a measure to the current, which, generally setting in on our shores from north to south, brings the seeds and plants themselves, of northern seas to our rocks, while those of southern growth are wafted by the same current to Africa and the Atlantic.

2308. *But few are the kinds of sea-weed which prefer any peculiar spot*, or show a predilection for one substance, above another whereon to fix. Deriving no nutriment from their roots or points of attachment, they need nothing farther than a temporary support ; thus, they cling indiscriminately to any solid marine body, equally to granitic and calcareous rocks, to floating or sunken pieces of wood, to the bones of terrestrial or marine animals, to shells, polypi, &c.

2309. *Notwithstanding that many highly respectable naturalists* have averred that the growth of these plants proceeds with most vigour on such and such substances, on some or other peculiar rock, in the vicinity of rivers, or in the open sea ; it has been fully ascertained, by a great number of observations, that marine weeds do grow with equal vigour, though planted upon rocks or substances of very different natures ; and that, if we except some few *Ulvæ*, which affect brackish water, those which vegetate in situations where fresh water mingles with the salt, are generally bleached, produce little or no fructification, have a thin and weak texture, and contain but little soda. The qualities requisite for the different uses of which I shall treat hereafter, are only found united in such sea-weeds as grow in pure sea-water, where they have found a spot which is sufficiently tenacious to fix them in that zone of habitation which they prefer.

2310. *Some kinds certainly prefer sand or mud* ; but then their roots become elongated, and strike deep, till they meet with some stone or shell or other body which may serve them as a point of attachment, and offer the requisite degree of resistance.

2311. *If the nature of the bottom appears indifferent, in a great measure, to marine plants* ; it is not so with the level which they select in the ocean, or with the distance of their birth-place from the surface. Every species of maritime vegetable appears to affect, to as great an extent as the terrestrial kinds, certain zones or regions of different depths in the sea ; places where the superincumbent weight of water, and the relative proportion of light and caloric, are adapted to its peculiar organs. Those individuals which are found towards the centre of their proper zone contain all the elements requisite for their perfect developement, and generally show an active state of vegetation ; they are vigorous, they fructify at the season suitable to their degree of immersion, while those which grow at the extreme limit, or out of the bounds, of this same zone, prove languishing, fructify imperfectly, are always covered with marine animals which destroy them, and live but a short time in comparison with their well-situated congeners. The seeds which escape from these plants would appear,

by their various specific weights, to gain an equilibrium equivalent to the column of water which they displace, or, in other words, to float in that peculiar zone which the future *Algæ* would prefer to inhabit. Those which become developed either above or below it, are inevitably driven from their spot of nature or of election, by the agitation in the waves at the vicinity of the coasts.

2312. Lower down than a hundred feet from the surface of the sea (taking a medium between the high and low tides) it is rare to find living sea-weeds in the Gulf of Gascony, and even these are attached to portions of rock severed from more elevated rocks, and before long they inevitably perish.

2313. It may be observed, that, the lower we investigate the sea, the fewer will the number of plants appear, and the more numerous the polypi. For instance, below forty feet from the surface of the water, but very few *Ulvæ* are found; beyond sixty feet no living *Ceramium*; and after having descended to the depth of a hundred feet, not a *Fucus* is to be seen, and the vegetable kingdom wholly ends.

1st Zone, extending from one foot above the medium height of the sea to twenty feet below, is inhabited by *Ulva compressa* var. β ; *U. intestinalis*, *ventricosa*, *Lactuca* var. α ; *Fucus pygmæus*, *amphibius*, &c.

2d Zone, from five feet below the medium height to thirty feet: — *Ulva articulata*, *Nostoc*, *bullata*, *fistulosa*, *Lactuca* var. β , *umbilicalis*, *lanceolata*, *purpurea*, *Linza*, *contorta*, *serrata*, *dichotoma*, *crispa*, *pavonia*, *atomaria* (?); *Fucus vesiculosus*, *spiralis*, *ceranoides*, *serratus*, *canaliculatus*, *cæspitosus*, *laceratus*, *hybridus*, *longissimus*, *pinnatifidus*, *viridis*, *arbuscula*, *fastigiatus*, *tenuissimus* (?), *confervoides*; *Ceramium spongiosum*, *rupestre*, *Mertensii*, *penicillatum*, *fucoides*, *nodulosum*, *gracile*, *linum*; *Zostera marina* and *mediterranea*; *Diatoma rigidum*, *flocculosum*, &c.

3d Zone, from fifteen to thirty-five feet below the medium surface. *Ulva ocellata*, *pal-mata*, *lingulata*, *polypodioides*, *caulescens*; *Fucus longifructus*, *lumbricalis*, *bifurcatus*, *ericoides*, *barbatus*, *abrotanifolius*, *vermicularis*, *norvegicus*, *obtusus*, *asparagoides*, *Wigghii*, *verrucosus*, *helminthocortos*; *Ceramium simplicifolium*, *casuarina*, *cancellatum*, *coccineum*, *incurvum*, *elongatum*, *polymorphum*, *forcipatum*, *filum*, *capillare*, *glomeratum*, *elegans*, &c.

4th Zone, from twenty to forty feet below the medium surface: — *Ulva Phyllitis*, *saccharina*, *digitata*, *bulbosa*, *ciliata*, *edulis*; *Fucus nodosus*, *uvarius*, *furcatus*, *ciliatus*, *alatus*, *plocamium*, *plumosus*, *corneus*, *gigartinus*, *aculeatus*, *plicatus*; *Ceramium verticillatum*, *equisetifolium*, *sericeum*, *scoparium*, &c.

5th Zone, from thirty to sixty feet: — *Fucus siliculosus* var. α , *purpurascens*, *ligulatus*, *pistillatus*; *Ceramium coccineum*, *ægagropilum*, &c.

6th Zone, from forty to a hundred feet: — The flattened Fuci; *F. siliculosus* var. β , *loreus*, *sanguineus*, *fibrosus*, *coronopifolius*, &c., and *Ulva tomentosa*, which is, in fact, a polypus.

SUBSECT. 3. Zoology.

2314. The zoology of France assimilates less to that of central than of southern Europe. Notwithstanding the narrowness of its separation from Great Britain, it possesses many animals unknown as natives, or even as visitors, of our island. With regard to quadrupeds this circumstance is not surprising; for any channel of the sea, however narrow, forms an insurmountable obstacle to the wanderings or migration of purely terrestrial species: while others, of a semiaquatic nature, are too small and feeble to effect the passage. These con-

233

THE WOLF.

siderations, however, are insufficient to explain the limited range of the smaller birds, hitherto found only upon the Continent. The distribution of insects is dependent, in a great degree, upon that of plants; and the numbers of both common in France, but unknown in Britain, are nearly proportionate; on the calculation that has been made of six species of insects to one of plants.

2315. Among the wild quadrupeds of France is the wolf (fig. 233.), which is still not uncommon in the wooded and mountainous districts: when pressed by hunger, it descends to the farms, and even attacks the inhabitants. The beaver is said still to exist in the

southern parts; and, probably, the wild boar may not be wholly extirpated from the existing forests. Bears were once common, while three or four of the smaller quadrupeds appear peculiar to France.

2316. Several interesting and beautiful birds unknown, or but rarely met with, in Britain, are here not uncommon; such as the wood-chat (fig. 234.), shrike (*Lanius rufus* T.), the grossbeak or hawfinch, the blue-throated warbler, and several others of the same family. In short, from the connection of this country with the central and southern kingdoms of Europe, the ornithologist might, probably, discover in France more than three fourths of all the continental birds.

2317. *The marine productions* of those provinces bordering on the Channel, as may be expected,

crú are of a middle or small

MITRA ZONATA.

without horns, and the wool is curled only at the ends. The *Berichonne* are likewise hornless, but are known by their long neck: the face is covered with wool; that on the body being fine, white, close, short, and curled. The *Roussillonne* is derived from the merino race; and has very fine wool, the filaments of the piles being twisted spirally. Lastly, the *Ardennoise* is horned, and bears a very fine fleece: this breed likewise extends over part of the Netherlands. (*Ham. Smith.*)

2321. *A large and elegant variety of the Domestic Cat* is very common in some parts of France; it is nearly double the size of ours, and is bearded much in the same manner as the lynx.

SECT. III. *Historical Geography.*

2322. *The Gauls*, the ancient inhabitants of France, and the chief among the Celtic nations, were an active, powerful, and ambitious people. Their emigrant hordes repeatedly crossed the Alps, possessed the whole north of Italy, once sacked the imperial city, and even penetrated into Greece and Asia Minor. Both Switzerland and Belgium were then included as part of Gaul. The people, though still barbarous, had made some steps towards civilisation. The nobles and Druids enjoyed high power and influence, and had reduced the body of the nation almost to a state of vassalage. They combated with obstinacy, and made a long resistance to the progress of the Roman arms; but being opposed to Cæsar, the greatest of the Roman captains, after a war of twenty years, they were entirely and permanently subjected.

2323. *The conversion of Gaul into a Roman province*, though it humbled the chiefs and quelled the martial spirit of the people, was attended with many beneficial changes. Peace was established; cultivation and industry promoted; Roman and even Greek literature introduced; and the people finally converted to the Christian faith.

2324. *The irruption of the Teutonic tribes*, on the decline of the Roman empire, was early felt in Gaul, where the Goths, the Heruli, the Burgundians, and the confederacy called the Franks, overwhelmed and ravaged the whole kingdom, and drove the Celtic population and language into its remote and mountainous corners. From amid a chaos of convulsions,

do not offer any marked difference from those of our own coasts; but on the warm shores of Nice and Marseilles the naturalist meets with numerous productions, indicative of the rich stores of the Mediterranean Sea. The entomology of these southern provinces, in like manner, presents us with many of those more striking insects which properly belong to the fauna of Italy. The beautiful *Papilio Podalirius* (fig. 235.) so rare in England that its existence with us is still doubted, is here a common insect. France has long stood foremost in promoting and illustrating the study of nature;

publishing a *Fauna Gallica*. An able and indefatigable naturalist, M. Risso, has particularly illustrated the fishes and crustacea of Nice. It was near this place that one of the rarest and most beautiful shells of Europe, the *Mitra zonata* (fig. 236.), was fished up by the anchor of a vessel: only one specimen is known to exist in collections.

2318. *Among the domestic animals*, the French horses are not very excellent; yet those used in the public stages are strong, active, and compactly made; nor have their masters copied our ridiculous and barbarous custom of disfiguring these animals, by cutting off their tails or ears. The stallions of England are much prized, and have been judiciously used to improve the native breeds.

2319. *The oxen are of two races*; the one called *bœufs de haut crú* are of a middle or small size, with a fierce look, thick hide, and coarse hair; they are principally bred on the mountainous provinces of Gascony, Auvergne, &c. The others are called *bœufs de nature*, and are larger, with a mild aspect, thin hide, and soft hair: they fatten easily, and belong to the plains.

2320. *The native breeds of sheep*, not in themselves good, have been of late sedulously and successfully improved. The Flemish breed, common both to France and the Netherlands, is generally hornless, with long legs, and is derived from an intermixture with those of Barbary. The *Solognot* are mostly

the vigorous hand of Clovis established the undisputed supremacy of the Franks, and founded the monarchy of France.

2325. *The reign of Charlemagne*, son and successor to Pepin, who from mayor of the palace had occupied the throne, formed the most brilliant period in French history. That eminent and powerful prince not only placed on his head the iron crown of Lombardy, but reduced to his dominion, after a long and obstinate resistance, the intractable tribes of Germany, who had defied the utmost efforts of the Roman eagle. He penetrated also into Spain; but the fierce encounter of the Saracens, and the disastrous adventure of Roncesvalles on his return, completely stopped his career in that direction. Charlemagne, though himself illiterate, made some efforts to rekindle the declining light of science and letters in Europe.

2326. *The contests among the successors of Charlemagne* were attended with the most violent and bloody convulsions, and with continual changes in the position of the three great kingdoms which composed his empire. At length it fell entirely to pieces. Germany retained the title of empire, and the claim to the dominion of Italy; and in France the Carolingian dynasty, or that of Charlemagne, having become extinct under Louis Outremer, the throne was seized by the Capets, the most powerful among the noble French families.

2327. *Hugh Capet*, having in 987 assumed the title of king, the real power attached to which had already been exercised by his father, Hugh the Great, founded the present dynasty. The administration, however, was long marked by a strong feudal character, and a high spirit of independence among the great nobles, of whom the counts of Provence and Britany, and the dukes of Burgundy, ranked altogether as separate and often hostile princes. The feudal age of France was also marked by chivalric and eventful wars with England, which long held several of the finest provinces, and whose king, Henry V., was crowned at Paris; but from that seemingly approaching downfall, the monarchy, through the romantic exploits of the Maid of Orleans, suddenly revived, and became more mighty than before.

2328. *The establishment of monarchical power* in its plenitude was chiefly effected by the profound and insidious policy of Louis XI., favoured by the circumstances of the age. All France was united under the sway of the kings, who were thus enabled to form great armies, which, under Charles VIII. and Louis XII., over-ran nearly the whole of Italy. But it was under the gay and enterprising reign of Francis I. that its energies were fully developed. It then, however, came into collision with the house of Austria, whose extensive possessions in Germany, Spain, the Netherlands, and Italy, wielded by a powerful hand, secured to it during this period a decided, though not overwhelming, ascendant.

2329. *The civil wars* arising out of the persecution of the protestants agitated France for a very long time, and produced scenes of the most bloody and calamitous description. They lasted for a hundred years; for the popular reign of Henry IV. could scarcely be considered as more than a truce. At length Richelieu, by the reduction of Rochelle, terminated the long struggle of the protestants for religious liberty, which in France alone, of all the countries where it was maintained upon a great scale, had this fatal issue. At the same time, this daring and despotic minister finally crushed the power and pretensions of the nobles, and formed France into a simple monarchy.

2330. *The reign of Louis XIV.*, during which a single hand wielded all the energies called forth during the prior struggles, exhibited France more powerful than she had been since Charlemagne. The house of Austria, now divided into the German and Spanish branches, of which the latter had become weak and inert, was humbled by repeated blows, which at length almost threatened her existence. France seemed advancing in the career of universal monarchy, when the interposition of England and the victories of Marlborough turned the tide of success, and rendered the last days of Louis humiliating and disastrous. The final issue, however, by which a Bourbon was placed on the throne of Spain, and the consequent family alliance, gave to France an increased weight, especially in the maritime concerns of Europe.

2331. *The French revolution* was an event attended with awful and mighty vicissitudes, so fresh in the memory of the world, that it would be quite superfluous to attempt to enumerate them. After tearing up France by the roots, and holding all Europe in chains; after exhibiting during twenty years the vicissitudes of republicanism, total anarchy, and pure despotism; at length, by a mighty re-action, it terminated nearly at the point from which it commenced. France, however, obtained checks on the arbitrary power of her monarchs, which, notwithstanding their opposition, she rendered more and more effective. At length Charles X., having rashly attempted to break through all the limits placed on his authority, was driven from his throne, which was filled by Louis-Philippe, head of the collateral line of Orleans, under the title of King of the French.

SECT. IV. *Political Geography.*

2332. *The political constitution of France*, prior to the Revolution, was almost purely despotic. The privileges of the nobles consisted nearly altogether in unjust exemptions

from taxation, and in *corvées*, or iniquitous and oppressive claims upon the labour of the peasantry. The only very salutary limit to the royal authority consisted in the parliaments, hereditary bodies, by whom the laws were very fairly and honourably administered; and the parliament of Paris had even the important privilege of registering every new tax before it could become legal. The exorbitant powers vested in the sovereign being however inconsistent with the growth of national intelligence and the augmented force of the *tiers état*, a collision took place, the most terrible on record, which ended in the temporary subversion of the throne. When the Bourbons were restored by foreign victories, they felt, and were warned, that France could no longer be governed by the former absolute system; and they bestowed by charter a representative government formed on the admired model of England. The nobles and parliaments, however, had been entirely swept away in the late convulsions, and left no hereditary aristocracy out of which an upper house could be composed. A Chamber of Peers was however formed, by the royal appointment, of a body of individuals, many distinguished rather by talents and influence than by birth; and in the number were included some of the most distinguished of Napoleon's generals. Pensions were assigned to support the dignity of the peers, which was at first hereditary, but by a recent enactment is to continue only for life. The Chamber of Deputies, corresponding to our House of Commons, is chosen by electors united in certain bodies called electoral colleges. These include all persons paying a certain amount of direct taxes; which limits the right of voting to the middling class, and to an entire number throughout France scarcely exceeding 130,000. The number of deputies is 430. The functions of the French chambers are high. Their annual vote grants all the supplies of the year, and all the expenditure of the preceding one is submitted to their rigorous examination. No taxes can be imposed, or loans contracted for, without their concurrence. Their debates are regularly made public, and an arrangement is enacted by law for the convenience of the reporters. Yet the chambers want some of the functions of a British parliament. They cannot fix the amount of the army, unless by limiting the funds to be employed in its maintenance; nor can they call in question the engagements held by government with foreign powers, unless by withholding the funds necessary to fulfil them. The liberty of the press was professedly granted by the charter; but there has been much fluctuation in its exercise; it was even repeatedly made subject to a censorship: but since the last great change, its freedom has been established on as ample a basis as in Britain.

2333. *The administration of justice in France*, which, before the Revolution, was still more complicated than in England, has been simplified in a very remarkable degree. The National Assembly early applied themselves to form a new series of codes, which might supersede those vast and voluminous records in which the law was formerly contained. They projected five codes, respectively referring to civil law, civil procedure, commerce, criminal law, and penal infliction. These were completed under Bonaparte, who gave to the whole the name of *Code Napoléon*: it is comprised in a moderate volume, sold for a few shillings. All the ancient parliaments and seignorial authorities being swept away, a new system of jurisdiction has been formed. Of the judicial authorities, the lowest class are the *juges de paix*, who amount to nearly 3000. They have salaries of 30*l.* or 40*l.*, and decide finally on all cases where the question at issue does not exceed fifty francs. Immediately above them are the tribunals *de première instance*, before whom all questions and charges come in the first instance, and who judge finally respecting any property not exceeding 40*l.* There are 360 of these courts, and the judges are supposed little short of 3000. To them are attached the tribunal of correctional police, which has cognizance of all minor offences. Above these rank the *cours royales*, sometimes called *cours d'appel*, because an appeal lies to them from the inferior courts. They are twenty-seven in number, attached to the chief cities in the kingdom. They consist, in populous towns, of twenty, thirty, and in Paris of fifty members; who, in that case, are divided into several chambers. Attached to them are the *cours d'assise*, or, as we would call them, jury courts, to which all criminal cases of importance are referred by the *cours royales*. A French jury consists of twelve, and a simple majority decides. From the decisions of the *cours royales* an appeal lies to the *court of cassation*, the highest tribunal, which also exercises a general jurisdiction over the other judicial bodies. All the judges are appointed by the crown, but hold their offices for life.

2334. *The results of criminal procedure* in the year 1829 were as follows:—There were accused, 8119 persons; of whom 7373 were present, and 746 absent. Of the former, 1971 were for crimes against persons, and 5582 for crimes against property. Of the present, there were condemned 5475; of the absent, 729. Sentence of death was pronounced upon 135; that of perpetual labour upon 346. Of the accused, 1442 were females; of whom 616 were acquitted, 10 were condemned to death, and 15 to perpetual hard labour. Of the 135 condemned to death, 46 had fled, leaving 89 liable to execution. Of these, 40 were for assassination; 8 for attempts to assassinate; 7 for poisoning; 3 for parricide; 7 for murder accompanied with another crime; 2 for attempts to murder; 6 for coining; 15 for fire-raising; 1 for robbery with violence. Of the 89, 60 were executed. The others had their sentence com-

muted. Of the 4475, 2827 could neither read nor write; 1160 could read and write imperfectly; 404 could read and write well; 81 had superior information; 3 unknown.

2335. *Financial system.* During the period of the Revolution, *France* shook off the heavy burden of debt which had been a main instrument in bringing on that catastrophe. Yet the amount of taxes had not exceeded 22,000,000*l.*, and the nation was crushed rather by the arbitrary and injudicious modes of levying the imposts, than by their actual amount. Napoleon, to support his continual wars, laid on large additional taxes, chiefly in the form of land assessment, and contracted, besides, 123,000,000*l.* sterling of debt. This was augmented by the events of 1815, and the occupation of the French territory by the allied armies at the expense of France. The debt is now expressed in the form of *rentes* or annuities, which in the budget of 1830 amounted to 249,496,000 livres (about 10,812,000*l.* sterling): this, with some other funds for which government were responsible, was considered as representing a capital of 4,988,738,000 livres (about 207,864,000*l.*).

2336. *The statement of receipt and expenditure for the year 1830 is as follows: —*

RECEIPT.		EXPENDITURE.	
	Francs.		Francs.
Direct Taxes, chiefly on Land	290,265,819	Civil List	27,666,666
Registration Stamps, and Domains	187,225,038	Chamber of Peers	799,999
Custom-houses and Salt	154,231,103	Chamber of Deputies	600,000
Liquors, Sundry Duties, Tobacco, and Gunpowder	193,081,582	Legion of Honour	3,655,209
Post Office	33,469,030	Sinking Fund	41,665,050
Falls of Timber	24,060,697	Funded Debt	276,356,668
Salt-works	1,200,000	Justice	19,566,020
Gaming-houses	4,338,888	Foreign Affairs	8,778,000
Royal Lottery	10,042,799	Religion and Public Instruction	38,961,500
Coinage	141,381	Interior	126,122,716
Sundry proceeds	11,585,418	War	233,363,817
Extraordinary resources	48,402,241	Marine	38,527,474
Deductions on Receipts	25,900,000	Finance	22,877,167
	983,944,066	Administration of Revenue	129,072,351
		Repayments	46,300,808
			1,064,288,445

2337. *The army of France* is no longer that vast and terrible mass, which for so many years held the whole of continental Europe in thrall. The events of 1815 having proved too clearly the attachment of the old troops to their former master, they were nearly all disbanded, and their place supplied by fresh conscription. The government has the power of levying 60,000 men in the year. By a regulation, breathing still the republican spirit, one third of the officers must be raised from the ranks. The army in the year 1832 was on a very formidable footing. It amounted in all, including 19,036 officers, and 3794 children of soldiers, to 411,816 men. Of these, the infantry consisted of 9505 officers and 264,141 men; the cavalry of 2805 officers and 51,335 men; the artillery of 1190 officers and 32,594 men, besides gendarmerie, engineers, &c.

2338. *The French navy*, which, in 1791, amounted to seventy-four sail of the line and sixty-two frigates, lost half during the war; and those which remained, having never ventured for many years to stir out of port, lost all their experience and efficiency. At present, they have a show of thirty-four ships of the line, thirty-nine frigates, and fourteen corvettes; but it would probably be very difficult to fit out for sea any considerable part of this force. The boasted flotilla of Napoleon does not seem to have left a shadow of its existence. In 1830, the entire number of persons employed in the navy amounted to 42,250; but of these 13,702 were labourers partly composed of criminals doomed to compulsory toil.

SECT. V *Productive Industry.*

2339. *France, with regard to internal economy*, is one of the richest and most flourishing countries in the world. In point of industry she ranks third after Britain and the Netherlands; while she possesses a greater extent and more natural advantages than either of those great seats of commerce and manufacture.

2340. *Agriculture* is the most flourishing branch, yet is not in so advanced a state as in Great Britain. It has gained greatly by the French revolution, in consequence of the abolition of feudal rights, *corvées*, and tithes. The great possessions of the nobility were then broken up, and during the grand emigration, the farmers, or neighbouring little proprietors and capitalists, were able to purchase at a very cheap rate portions of the forfeited domains. It has become a rage in France for every one to possess a little spot of land; and the division of a man's property among his children, which the law enforces, tends to split it perpetually more and more into minute portions. Travellers have even observed three or four proprietors obliged to join in keeping a common plough. In vineyards and other garden cultures, where nice care and diligence are chiefly requisite, this minute partition seems advantageous. Chaptal even calculates, that a small vineyard cultivated by the proprietor's own hand will yield double the quantity of that which is leased out by a large proprietor. But in corn lands, where a considerable capital, good machinery, strong and well-fed cattle are necessary, the cultivation is thus kept down to a much lower standard than it would otherwise reach. The little occupants, also, are by no means prompt in discovering any

improved processes, or in adopting those discovered elsewhere. Artificial grasses, and the rotation of crops which they facilitate, are by no means generally diffused; and an old vicious circle, of wheat, oats, and fallow, is still very generally adhered to. In short, all operations on a great scale, and requiring a considerable outlay, are deficient in France. M. Dupin, in a discourse on the effects of public instruction, in the introduction to his normal course of lectures on geometry, has drawn a striking contrast between northern and southern France. Although the former produces neither the olive, the vine, nor any of the finer fruits, yet it pays of taxes 127,630,000 francs on a surface of 18,690,000 hectares; while the south pays only 125,410,000 francs upon 34,840,000 hectares. Even in the south, the districts least favoured by nature are both the most enlightened and the most industrious; the high Alps, the high Pyrenees, and the departments immediately adjoining to them.

2341. *Grain*, notwithstanding the imperfections in its cultivation, is produced with such diligence as to yield enough in ordinary years to supply the extensive population of France with food. The only exception is in part of its southern coast, which, when permitted, draws a supply from Odessa. France is not distinguished for any very superior quality of grain, nor is it an exporting country. It seems to have attended less than most other countries of Europe to the culture of potatoes, which are still planted only in gardens, along borders, or in tracts unfit for grain. Maize is mixed with wheat in the southern departments. Chaptal has given the following statement, calculated on an average of twelve years, from 1800 to 1812, of the entire products of this branch of French agriculture:—

	Hectolitres.
Wheat	51,500,200
Rye - - - - -	30,290,161
Maize - - - - -	6,302,316
Buck-wheat - - - - -	8,409,473
Barley	12,576,603
Potatoes - - - - -	19,800,741
Oats - - - - -	32,066,587
	160,946,081

2342. *A more recent estimate*, in a memoir read to the Society of Statistics in 1830, makes the average produce of the years 1825 to 1828 amount to 60,553,000 hectolitres of wheat; 114,733,000 of other grains; 46,238,000 of potatoes and chestnuts.

2343. *Wine* ranks next in importance to grain, and forms a most valuable part of French industry. The wines of France, though not so strong as those of more southern climates, are generally accounted the most delicate in the world. Those of Burgundy and Champagne are without a rival, if we except a few rare specimens of Tokay. The wines of the Garonne do not rank quite so high; but, from their light, safe, and agreeable qualities, are drank more freely, and exported on a larger scale. The finest and strongest of these wines are cultivated chiefly to supply the consumption of Britain and the other northern nations. The interior consumption of France consists chiefly of the light wines, drank at table, nearly as our beer. Two elaborate attempts have been made to estimate the produce of the French vineyards; one by Chaptal, in his "General Treatise on French Industry," and the other in the report of a committee of the Chamber of Peers, presented in 1824 by the Duc de Dodeauville. They differ pretty considerably. Chaptal supposes that 1,631,000 hectares are employed in producing wine to the average annual amount of 35,500,000 hectolitres. The table, however, given by the duke, of the produce of each department does not exceed 31,630,000 hectolitres. The difference as to value is still more remarkable. Chaptal, after leaving out a sixth, as made into brandy, estimates the remainder at 678,000,000 francs (28,000,000*l.* sterling): he supposes that there are 800,000 worth each 200 francs; 1,600,000 worth 50; gradually descending till he comes to 10,500,000 worth only $7\frac{1}{2}$ francs. Dodeauville does not bring the amount to more than 480,000,000 (20,000,000*l.* sterling). The highest average value he assigns to the wines of any department is to those of the Oise (champagne), 36 francs; those of the Marne, Yonne, and Côte d'Or (burgundy), 26 to 24; of the Gironde, and Lot et Garonne (claret), 19 to 21; the rest from 17 to 9. His estimate, however, seems too low; since M. Dupin (*Forces Productives, &c. de la France*) calculates the value, according to the tax paid to government, at 543,155,078 francs (about 23,000,000*l.* sterling). The brandy into which one sixth of the above produce is made, is, like the wine, the finest in the world, and a grand staple of French trade. Chaptal estimates the value distilled at 40,000,000 francs (1,750,000*l.*). M. Dupin states the quantity at 469,817 hectolitres; that of other spirits at 90,000. He calculates also 8,868,218 hectolitres of cider, worth 2,760,000*l.*, and 2,965,022 hectolitres of strong beer.

2344. *Live stock* does not form the most approved part of French husbandry. Chaptal considers that the animals are too few, whether for culture, for use, or for the production of

manure ; and also that the measures taken to improve the breed have been very partial and defective. The number of horses, including mules, in 1827, was 2,550,000. Of these it was reckoned that 300,000 were employed in riding, posting, the artillery, &c. The stock requires to be kept up by an importation, which in 1809 to 1812 was valued at 3,541,000 francs annually, but according to M. Senac had risen, in 1822 to 1825, to 7,500,000. In return, there is an extensive breeding of mules on the Pyrenean frontier, and they are exported to Spain to the value of 1,400,000 francs. France had in 1812, 214,000 bulls, 1,701,000 oxen, 3,909,000 cows, 856,000 heifers. The importation at that time amounted to only 2,360,000 francs, but in 1825 it was 7,680,000. The exportation is, however, considerable. Sheep are a species of stock very considerable in amount, particularly in the departments bordering on the Alps and Pyrenees, in those which compose the mountain district of Auvergne, and on the pastoral banks of the Eure and the Cher. The number of sheep in 1812 was 766,310 merinos, 3,578,000 mixed, and 30,843,000 native or unimproved. The first introduction of merinos was in consequence of the treaty of Basle, which stipulated that 4000 of these highly prized animals should pass into France. An experience of thirty years has shown that the breed might be preserved and extended in full perfection ; but the above statement will show that the diffusion of it is, as yet, very partial. Pure merinos are valued at thirty francs, mixed at twelve francs, and native sheep at only five francs. The number of swine in France is estimated by Balbi, in 1826, at 4,000,000. The ass is considered by M. Senac to be, from the poverty of his owners, in an almost hopeless state of degradation ; and the fowls, the bees, and the pigeons to demand a thoroughly improved system of rearing. Chaptal has not attempted to estimate the winged species, but has guessed their entire value at above 2,000,000*l.* sterling.

2345. *Among the materials of manufacture*, the most important is silk, which was at first introduced near Tours, but was soon found to be well suited only to the most southern districts. The amount, according to Chaptal, is about 11,400,000 lbs., and the value 15,440,000 francs ; but this is only about two fifths of the quantity consumed in the manufactures, so that a large importation is necessary from Lombardy. Hemp and flax are cultivated universally, but always on a small scale, every farmer having his little patch for domestic use. It is difficult to estimate these ; but Chaptal guesses the value of hemp at 1,250,000*l.*, and flax at 800,000*l.* Vegetable oils are produced to the supposed extent of 1,300,000 quintals, worth about three millions sterling ; yet so great is the quantity consumed in domestic use, and in the different manufactures, that they are imported to the value of nearly a million.

2346. *There are certain tropical and colonial productions* which it was the eager wish of Napoleon that France should cultivate, in order that she might be independent of commerce. One of his favourite projects was the culture of the beet root, for the extraction of sugar, an article of consumption with which Europeans can least dispense. The admission of colonial and foreign sugars, under reasonable duties, after the overthrow of the continental system, gave a severe check to this spurious branch of industry. To prevent its decline, heavy additional duties were laid on colonial and foreign sugars in 1816 and 1822 ; and, in consequence of this encouragement, the production of beet root sugar has been rapidly increasing during the last five years, and is now supposed to amount to about 8000 tons, or 8,960,000 lbs. The art has been a good deal improved ; and it is supposed by many that it will, at no distant period, be so much ameliorated that the beet growers will be able to withstand the competition of the West India planters under the same duties : but any such expectation seems to us to be quite visionary. The entire consumption of sugar in France amounts, at present, inclusive of that from the beet root, to about 72,000 tons a year ; being not much more than a third part of the consumption of Great Britain and Ireland, which amounts to about 190,000 tons. Tobacco, after the removal of the *régie* or royal monopoly, rose to 50,000,000 lbs. ; but since the restoration of the *régie* in 1812, it has fallen to 5,000,000.

2347. *Wood* is an important article, especially in a country which is nearly destitute of any other fuel. Chaptal estimated the woodlands at 7,072,000 hectares (about 17,500,000 acres) ; but according to a more recent memorial in 1824, by M. Herbin de Halle, sub-administrator of the forests, it is only 6,521,000 hectares (about 16,000,000 acres). Of this, 1,122,000 hectares belong to the state, 1,896,000 to the communes, 65,969 to the crown, 192,000 to princes of the royal family, and 3,243,000 to private individuals. Woods thus occupy a little more than an eighth part of the soil. The greatest proportion exists in the departments bordering on the Alps and the Pyrenees, and along the Rhine, the Moselle, the Saône, the Marne, and other eastern rivers. Chaptal estimates the value of the annual cuttings at about 6,000,000*l.* sterling ; but if this be reduced according to M. de Halle's estimate, it will give only five and a half. Fruit trees are also of importance, especially chestnuts, cultivated on a large scale in several provinces, and valued by Chaptal at about 400,000*l.* He estimates the fruit growing open in orchards at 900,000*l.*, and that on walls, or in rows as single trees, at 2,750,000*l.* He is afraid that this last will be thought too low ; we should rather apprehend an opposite error in this instance, as well as in that of reckoning the herbs which grow in 328,000 hectares of garden ground, at 8,000,000*l.* sterling.

2348. *On the whole, Chaptal calculates that in the 52,000,000 hectares of which France consists, twenty-three are arable; ten woods, vines, fruit trees; seven pasturage; the rest waters, roads, buildings, waste. He makes the annual average produce of an acre 28 francs (1l. 3s. 4d.). By this and other estimates, the annual territorial produce comes to very nearly 60,000,000l. sterling. In estimating the entire agricultural capital, he considers the land itself with the wood upon it to be worth 1,386,000,000l., the live stock 66,000,000l.; agricultural implements, machinery, and farm houses, 126,000,000l.: in all, 1,578,000,000l. M. Dupin, in 1827, reckons the territorial revenue at 1,626,000,000 francs (67,750,000l.).*

2349. *The manufactures of France, though they do not present the immense results of those of England, are considerably more productive than those of almost any other nation. Colbert, the celebrated minister of Louis XIV., finding this branch in a very depressed state, compared with its prosperous condition in some neighbouring countries, bestowed on it almost an exclusive attention. Chaptal calculates, that during the Revolution it made still greater progress than agriculture. He regards as almost miraculous the advance made in the cotton and other fabrics. The miracle, however, was wrought solely by the rigid exclusion of British goods; and amid all the boasted proofs of French ingenuity, he is obliged to confess, that when, as minister of the interior, he sought eagerly the means of introducing new manufactures, he could find no effectual expedient, except that of alluring English manufacturers into France, and of copying their processes. However, these prohibitions, which have been continued to a great extent under the royal system, have in fact forced a number of manufactures which could not otherwise have withstood British competition.*

2350. *Silk has been long one of the most prominent objects of French manufacture. Even the revocation of the edict of Nantes, though it drove many of the most industrious citizens out of the kingdom, left that branch of industry still very flourishing. It suffered more from the dreadful calamities which befell Lyons, its chief seat, during the height of revolutionary mania. The 15,000 establishments that existed in 1788 for the manufacture of silk, were reduced in 1800 to 3500; but amounted, in 1831, to about 15,000, employing above 21,000 workmen. It is chiefly in cloths that this city excels all others, both as to the brilliancy of the dyes, and the richness and beauty of the stuffs. Nismes excels in taffetas, mixed silk and cotton stuffs, gauzes, and crapes; Tours in furniture stuffs; Avignon in satins, levantines, &c. The Cevennes are famous for bonnets, while almost all the silk ribands are fabricated in the department of the Loire. The entire value of the manufacture is estimated at 5,000,000l. sterling, of which 1,250,000l. is exported.*

2351. *The woollen manufacture is still more extensive and valuable than that of silk. The woollens of France are either very coarse or very fine; the former are established chiefly in the hilly tracts of the southern border, where the sheep yield abundance of coarse wool, and the shepherds spend the leisure of winter in working it up into serges, friezes, and similar stuffs. On the other hand, at Sedan, Louviers, Abbeville, are manufactured finer cloths than any of those of Britain, though we produce a much larger quantity of good and substantial cloth. Although France produces 84,000,000 lbs. of wool, she yet imports to the value of 12,000,000 or 14,000,000 of francs: Chaptal estimates the whole unmanufactured wool at 93,000,000 francs, and the finished work at 238,000,000, or nearly 10,000,000l. sterling, of which the exports amount to about 1,000,000l.*

2352. *The making of linen is as widely scattered as the culture of hemp and flax. The coarse cloths are chiefly fabricated by the peasantry, each out of the produce of his own little patch of land. There are, however, large manufactures of plain useful cloth in Normandy and Dauphiné, the latter from hemp; and great quantities of sailcloth are made in the maritime counties. In the departments along the Belgic border there are extensive fabrics of lawns, cambrics, and lace; which last, though not of equal reputation with that of Brussels and Mechlin, forms yet an important object of trade. Chaptal reckons the raw material of hemp at 1,500,000l. sterling; the finished manufacture at nearly 4,500,000l.; flax, raw material, 850,000l., the finished fabric, 3,100,000l. The exportation is about 1,500,000l., almost wholly of the finest kinds of the manufacture.*

2353. *The cotton manufacture was established in France during the continental system; and has been propped up since the restoration of the Bourbons by the prohibition of importation from abroad. In 1810 the imports of raw cotton amounted to above 25,000,000 lbs., and during the next ten years they were more than doubled. But the high price of machinery in France, the scarcity of coal, and the want of skill on the part of the workmen, seem to oppose almost insuperable obstacles to the further progress of the manufacture. It is at present in a very depressed state, and the following account shows that it has been nearly stationary during the last ten years:—*

Imports of Cotton Wool into France:—

	lbs.		lbs.
1822	- - - 61,758,300	1827	- - - 87,185,100
1823	- - - 50,953,500	1828	- - - 61,839,600
1824	- - - 75,322,200	1829	- - - 72,669,000
1825	- - - 61,371,600	1830	- - - 84,825,600
1826	- - - 96,052,200	1831	- - - 65,517,900

2354. *Of the secondary objects of manufacture*, that of leather is perhaps the most extensive, though not peculiarly French. It is supposed that in France the annual product amounts to 857,000 cow-hides ; 110,000 horse-hides, and 2,032,000 calf-skins. There are 31,000 shoemakers in Paris, who make upwards of eight millions of pairs of shoes yearly, not only for the city itself, but the provinces, and even foreign countries. Chaptal reckons the whole produce of tanning, currying, shoemaking, and all processes connected with leather, at 6,000,000*l.* Hard soap was formerly supplied by Marseilles to all France and the colonies, but its produce of 225,000 quintals is now reduced by a third ; owing partly to the reduction of the colonial demand, and partly to the more general diffusion of the manufacture. It is thought still to amount to 1,250,000*l.*, with 120,000*l.* value of soft soap made in the northern departments. Starch, including hair-powder, may amount to 18,000,000 pounds, and its value to 250,000*l.* There are sundry little matters of jewellery, trinkets, furniture, perfumery, scented waters, volatile salts, which elsewhere are only petty trades, but which taste and fashion in France raise to the dignity of manufactures, the whole produce of which is reckoned at upwards of 4,000,000*l.* sterling. Crystal, glass, and pottery are branches in which the French have recently made great progress ; and, from being dependent on foreigners for these articles, are now able to export them. The first two branches are estimated at 850,000*l.* ; porcelain made at Sèvres and other places at 200,000*l.* ; pottery in imitation of English a little more ; coarse pottery for the lower ranks, 600,000*l.*

2355. *Mineral kingdom.* France yields in abundance the most solid and useful of all metals, iron. There are about 400 forges in the kingdom, chiefly in the Pyrenean and Alpine departments, and along the heads of the Marne, the Moselle, and the Saône.

2356. *The produce* which M. Chaptal reckoned only 81,000,000 kilogrammes, had, according to M. Dupin, risen in 1825 to 161,000,000 (about 161,000 tons), the value of which would be above 3,000,000*l.* sterling. Chaptal supposed the workmanship bestowed even on the smaller quantity produced in his time sufficient to raise the value to 8,000,000*l.* Nearly all the copper and lead employed in France is imported from abroad. Salt is extracted on the southern coast from sea-water evaporated by the heat of the sun, and in the north from brine-springs artificially evaporated. During the period when salt, relieved from the old oppressive monopoly, was left entirely free, its production and use rose to the extraordinary height of upwards of 20 millions of quintals. Since the re-establishment of the tax, it has fallen to not quite two millions ; upon which there is paid a duty of 1,800,000*l.* This astonishing diminution seems chiefly owing to the disuse of it in agriculture ; a circumstance however very injurious to that branch of industry. Other mineral products, with their supposed value, are, alum, 100,000*l.* ; saltpetre, 120,000*l.* ; nitric acid, 240,000*l.* ; muriatic acid, 10,000*l.*

2357. *The total value of the products of the mines and manufactures* of France is estimated by Chaptal at 75,835,000*l.* sterling. The particulars are, about 17 millions of home raw materials ; 8 millions of foreign raw materials ; 35 millions of workmanship ; 8 millions of general expenses, as implements, repairs, lighting, interest of fixed capital ; 7½ millions for the profit of the manufacturer.

2358. *The commerce* of France, while all the other branches of industry were thus advancing, has perceptibly declined. It was reduced, indeed, to a state of temporary annihilation by the violent policy of Napoleon, who absolutely lined the coast with troops, that not a single vessel might enter. Thus all the commercial ties of France were broken, every channel closed by which she was accustomed to exchange her commodities with those of foreign countries. Indeed, the anti-commercial spirit seems to have become rooted in the mind of the nation ; and when we find even the enlightened mind of Chaptal extolling the prohibitory system, and considering every thing as a source of loss to France which she imports from abroad, there can appear little prospect of any amendment. That writer considers the year 1789 as the most flourishing period of French commerce ; when the exports amounted to 18,200,000*l.* sterling, and the imports to 26,500,000*l.* This extraordinary excess of imports, a result, according to old ideas, considered so disastrous, he explains by observing, that the imports include ten millions from the colonies, while the exports thither were only four, and also two millions and a half in gold and silver. Whether this explanation be sound or otherwise, we have no idea that there could be any permanent or extensive difference between the two branches. Chaptal has, with grief, declined to give any record of the feeble efforts at revival made by the French commerce. Since the appearance of Chaptal's work, however, it has considerably improved. In 1827, the import trade was carried out by 3350 vessels under the French flag, tonnage 353,000, value of cargoes 230,140,000 francs ; and by 4439 foreign vessels, tonnage 474,000, value of cargoes 136,041,000 francs. There were, besides, imported by land, goods to the value of 199,621,000 francs ; making the imports in all, 565,802,000 francs (23,500,000*l.*).

2359. *In the same year* the export trade was carried on by 3522 French vessels, tonnage 346,000, value of cargoes 235,120,000 francs ; and 4141 foreign vessels, tonnage also 346,000, value of cargoes 167,728,000 francs. The exports by land amounted to 156,767,000 francs ; making in all, 559,615,000 francs (23,300,000*l.*).

2360. *The following was the value of the leading articles of import and export : —*

IMPORTS.		EXPORTS.	
	Francs.		Francs.
Raw hides	8,700,000	Dye stuffs	8,300,000
Wools	11,140,000	Gems	2,120,006
Feathers	1,580,000	Horses	1,290,000
Silks	32,270,000	Mules	4,840,000
Tallow	2,500,000	Sheep	1,420,000
Fruits, to plant	1,220,000	Horned cattle	2,520,000
Tobacco	7,650,000	Refined sugar	4,550,000
Vegetable juices	2,270,000	Wine, ordinary	41,510,000
Oils, not for food	21,430,000	—, liqueurs	5,720,000
Medicines	2,130,000	Brandies	22,970,000
Wood	17,000,000	Strawhats	2,090,000
—, ornamental	2,900,000	Porcelain	3,680,000
Hemp	4,210,000	Glass	2,600,000
Flax	56,000	French books	3,140,000
Cotton	51,910,000	Paper	3,960,000
Gems	8,200,000	Perfumery	5,390,000
Sulphur	1,290,000	Cloths, wool	26,920,000
Coal	8,080,000	—, silk	90,860,000
Cast-iron	1,170,000	—, ribands	24,380,000
Copper	9,110,000	—, cotton	46,020,000
Tin	2,130,000	—, linen	17,370,000
Potash	3,420,000	Cambric and lawn	16,580,000
Indigo	14,880,000	Plaqué	3,170,000
Horses	3,360,000	Clock and watch-work	4,240,000
Sheep	6,400,000	Tabletterie	3,790,000
Horned cattle	2,520,000	Mercery	6,880,000
Butter	1,960,000	Modes	2,300,000
Eggs	3,830,000	Made clothes	6,480,000
Grain	7,150,000	Parisian articles	5,690,000
Cheese	3,140,000		
Fruits	16,200,000		
Sugar	36,000,000		
Coffee	10,000,000		
Straw-hats	4,550,000		
Linen, or hemp stuffs,	15,880,000		
Mercery	2,170,000		

2361. *Mercantile navy.* In 1827, the mercantile navy of France consisted of 14,530 vessels, of the burden of 700,000 tons. Of these there belonged to —

	Ships.	Tons.	Ships.	Tons.
Bordeaux	431	77,000	Nantes	537
Marseilles	711	65,000	Rouen	254
Havre	359	62,000	Dunkirk	229

2362. *The interior commerce* must be very extensive, though it is difficult to estimate its amount, as, notwithstanding considerable advantages for navigation, the bulk of it is carried on by land. The old medium of *fairs* has been not only preserved, but greatly extended. M. Bottin, upon documents furnished by the minister of the interior, calculates that there are 26,314 fairs in France. Some of these are held on the frontier of a province or kingdom, others round a great cathedral or noted place of pilgrimage; some at the foot of high mountains on the melting of the snows, which have kept the inhabitants imprisoned for several months. Sometimes they open with burlesque representations, as processions of giants, of flying dragons, or monstrous fishes. The fair of Longchamps, held in spring at Paris, those of Beaucaire in Languedoc, and of Guibray in Normandy, are the most extensive.

2363. *The canals of France* were long entirely undertaken by the government, which carried on these works with some spirit. The earliest was the Canal of Briare, to unite the Seine and the Loire. It is about 18 miles long, 4 feet deep, has 40 locks, and cost 400,000*l.* The canal of Languedoc is on a much greater scale, and was considered in its day a stupendous undertaking. It was intended to unite the Mediterranean with the Atlantic, and is 130 miles long, 6½ feet deep, with 100 locks. The cost was 750,000*l.*, which would have been, at least, doubled had the work been executed in the present day. It was considered the largest canal in Europe, till it was eclipsed by the Caledonian, which is three times as deep, and admits ships of war; whereas the canal of Languedoc has afforded a mere inland navigation, along which pass 1900 vessels of 100 to 120 tons; but it has not, for the most common merchant vessels, superseded the necessity of going round by the Straits of Gibraltar. The Canal of the Centre, joining the Saône and the Loire by a line of 70 miles, was completed in 1793, at an expense of 410,000*l.*; but only 5 feet deep. The Canal of Picardy, from the Oise towards Lille, remarkable for its long tunnel near St. Quentin, was completed in 1810, at an expense of 475,000*l.* Still, France, in this grand national improvement, remained far behind England, which, by M. Dupin's estimate, made a few years ago, had more than four and a half times as much canalisation in proportion to its surface. Very recently, however, France has displayed an extraordinary activity in planning, and a considerable diligence in executing, designs of this nature. This too has been displayed not by government only, but by private associations, asking only aid and advances from the state. Independent of the finished works above stated, twelve great new canals are in progress. These are, — 1. The Canal

Monsieur, joining the Rhine and the Rhone by the Saône and the Doubs; length 180 miles. 2. Of Burgundy, joining the Saône to the Loire by the Yonne, 145 miles. 3. Of Angoulême, making the Somme navigable to Amiens. 4. A lateral canal along the Loire, to avoid the difficulties of its navigation, from Dijon to Briare, 120 miles. 5. From Nantes to Brest, with a view of provisioning the ports of Britany, 220 miles. 6. Of Ille et Rance, joining Nantes to Brest and St. Malo. 7. Of Nivernois, joining the Yonne to the Loire. 8. Of the Duke of Berri, joining the Cher to the Upper Loire. 9. Ardennes. 10. Blanet. 11. Arles. 12. Oise. The estimates for completing these twelve canals were within a trifle of 10 millions sterling, of which, in March, 1829, there had been expended 6 millions. Several canals, on a still more magnificent scale, have been recently contemplated, and what the French call the *études* of them are even far advanced; but no part of the works has yet been commenced. Doubts are even entertained if they will repay the immense expense required for their completion. The principal of these are, — 1. A maritime canal from Paris to the sea, avoiding the circuitous navigation of the Seine, and admitting ships of large burden to that capital. The estimate is 6,000,000*l.* sterling, and 600,000*l.* for a harbour at Paris. 2. A canal from Paris to Strasburg; which would become, as it were, the French Grand Trunk, and might easily be extended to the Danube. The length would exceed 300 miles, and the estimate is nearly 3,000,000*l.* sterling. 3. The Pyrenean Canal, from Toulouse to Bayonne, forming a more direct communication from sea to sea than at present. Length, 210 miles; estimate, 2,400,000*l.*

2364. *The roads of France*, at least the high roads, have been chiefly supported by government. They are broader, more spacious, more direct, and on the whole of grander aspect, than the English roads; but they have not been kept in such good condition for travelling. Roads have been made and repaired rather for political and military purposes, from solicitation and favour, than for objects of real utility. The system seems to have been, to neglect them as long as possible, till the clamour of the district became irresistible, and then to give them a thorough repair; to which Dupin justly prefers our system, of keeping roads constantly in a good state by small repairs as the necessity arises. The French roads, however, have been greatly improved since 1810, and the maintenance of a great proportion of them has been undertaken by the departments; so that they are now divided into royal and departmental. The royal roads, in 1828, extended 8631 leagues, and there was expended on them 199,000,000 francs, or upwards of 8,000,000*l.* sterling; but this was chiefly on repairing and extending different parts of them. It was thus divided: —

	Francs.
To maintain 4205 leagues, cost	- - - 9,349,000
To repair 3166 ditto	- - - 61,051,000
To complete 814 ditto	- - - 43,403,000
To open 446 ditto	- - - 34,964,000
Works of art	- - - 50,696,600
	199,463,000

2365. *The departmental roads*, in 1828, extended 7704 leagues, of which 6040 had been opened, and to complete the remaining 1664 would require an expenditure of 4,500,000*l.*

2366. *Of the bridges of France* several are handsome, as those over the Loire at Orleans, Tours, and Nantes; over the Seine at Paris, Neuilly, and Rouen; over the Rhone and Saône at Lyons; and over the Garonne at Bordeaux. Bridges of suspension have been commenced at Paris in front of the Hôtel des Invalides, and over the Rhone, between Tain and Tournon. These operations have been entirely in the hands of government. According to the report of M. Regnay, the support of bridges and aqueducts constructed would be 260,000*l.*; that of repairs, 340,000*l.*; completion, 300,000*l.*; new works contemplated, 1,650,000*l.*

SECT. VI. *Civil and Social State.*

2367. *The population of France*, which in 1780, by the enquiries of Necker, appeared to be 24,800,000, was found by the census of 1791 to amount to 26,363,000; by that of 1817, to upwards of 29,000,000; and by that of 1820–21, to 30,616,000, including Corsica and the army. According to the royal ordonnance of March 15th, 1827, it amounted to 31,851,545. There were in that year 965,634 births; of which 898,329 were legitimate, and 67,305 illegitimate. The births consisted of 498,177 boys, and 467,457 girls. The marriages were 229,613, the deaths 772,428. At an average the proportion of male births in France to female births is as 16 to 15; the marriages are to the population as 1 to 133; the births are to the marriages nearly as 4 to 1; and to the population as 1 to 31.53; the deaths are to the population as 1 to 39.4. The extraordinary improvement since 1780 in the condition of the people is obvious from the fact that at the last-mentioned period the deaths were to the whole population as 1 to 30.2: so that while, in 1780, one individual died annually out of every 30 individuals, in 1832 one only died out of about 39.

2368. *The French national character* has very marked features, and has been the object

of mingled admiration and contempt to the neighbouring nations. In the eyes of Frenchmen, especially of the old school, *la belle France* is the centre of all that is refined and polished in human existence, and whatever lies beyond its sphere is marked with a deep taint of barbarism; while their rougher neighbours brand them as artificial, effeminate, and fantastic. The art of living in society seems certainly carried to greater perfection than in any other country; and the manners are characterised by a peculiar gaiety, amenity, and courtesy. The polish of the higher ranks seems to have descended even to the lowest circles. "The man who breaks stones upon the road takes off his hat to the woman that leads her cow in a string; the tinker and the shoeblack whip off their hats to each other." A certain openness and kindness of disposition, called *bonhomie*, is certainly evinced in the custom of whole families, with married sons and daughters, continuing to dwell under the paternal roof. The Frenchman lives as it were in public: his house, for a part of the day, is open to a large circle of acquaintance. He enjoys society without expense and ceremony. He resorts habitually to the theatre, spectacles, and scenes of public amusement. In more serious points of view, the French possess estimable qualities. Intoxication is a vice confined to the lowest ranks; and swearing is repelled at least as a mark of barbarism. The French are ingenious, acute, active, and intelligent. If they have not what can strictly be called patriotism, they have at least a very strong national feeling. To exalt the glory and promote the influence of *la grande nation*, is the prevailing impulse which actuates the mind of almost every Frenchman. After all, we on this side of the Channel allege, that there is a want of that sterling principle, that openness and integrity, which forms the boast of the English character. Dissimulation and insincerity seem widely diffused through the intercourse of the higher circles. The honesty of the lower classes is, however, remarkable; and that system of higgling in shops, so offensive to an Englishman, is a consequence of the contracted state of commerce; and was, at no distant period, quite as common in Scotland. The deportment of the female sex, however embellished by *tournure* and the graces, does not accord with our ideas of social and domestic propriety. The young ladies are strictly watched, and held in almost monastic seclusion; but the era of marriage is the signal, if not of positive irregularity, at least of a system of regular flirtation, which we cannot reconcile to the conjugal and matronly character. It is probable, however, that the impression of the general dissoluteness of French manners has been chiefly derived from the opulent circles of the capital; while, as a late writer has observed, Paris and the provinces form entirely separate worlds. Among the peasantry, and even among the trading class in the cities, there appears to be much that is respectable and amiable. The great activity and prominent station of the female sex is every where conspicuous: they are seen managing the shops, carrying on great manufactories, and joining in the hardest toils of the loom and the field. It is not at all uncommon upon a farm to see the master sowing, his wife guiding the plough, and a fine girl filling the dung cart. Such avocations divest the fair sex in the provinces of any great portion of beauty. Indeed, the gay hilarity of the French character does not seem quite so universal as is generally supposed in England. Travellers in the south, from Arthur Young to those of later date, complain rather of a singular gravity and taciturnity. Mr. Matthews remarks, in his "Diary of an Invalid," that a very considerable change of manners has taken place since the Revolution. All the distinctions of rank have been cut down like the old trees of the forest, and the new generation, like the coppice, are all on a level. "You will seek in vain," he says, "for that high-bred polish of manners which has been so much boasted as peculiar to the *haut-ton* of France. A republican spirit prevails, and shows itself in an independent roughness of manner, savouring of *sans-culottism*." The tone of society among the body of the people has even been compared to that in the United States of America.

2369. *The Roman catholic has been the ruling religion in France*, ever since the fatal issue of the long struggle for religious liberty. Previously to the Revolution, however, a general scepticism pervaded all the well-informed classes, both as to the catholic tenets, and as to religion in general. This was doubtless one great cause both of the Revolution and of many of the fatal and disastrous aspects which it assumed. A furious anti-religious fanaticism reigned; all form of public worship was suspended, and even prohibited; the churches were rifled and defaced in a barbarous manner. At this time, the vast domains of the church, by which so many dignitaries and so many convents were supported in splendour, were voted the property of the nation, and sold at a low price to supply its necessities. Napoleon had the merit of re-establishing religious worship, and on a very liberal footing; an allowance being made for the support of the protestant clergy, proportioned to the number who still hold that faith, and who amount to about 1,500,000. As all the former funds however had disappeared, the establishment is supported out of the public revenue, and is frugal, and even scanty, both as to numbers and salary. There are five cardinals, with 1300*l.* a year; eighteen archbishops, with an annual income of 800*l.*; seventy-four bishops, 600*l.* After the intermediate classes of vicars and canons come the *curés*, or parish priests, amounting to 3000, with incomes of 40*l.* to 60*l.*; but the chief labour devolves upon 23,000 *vicars*, or acting curates, who starve upon 20*l.* or 30*l.* a year, with the addition of only

some small fees. The whole church expenditure, in 1823, amounted to 1,575,000 livres; but in 1832 was reduced by a third; and the church has been in a somewhat unsettled state. The Bourbons were supposed to aim at restoring it to all its former power, splendour, and privilege; a course viewed with extreme jealousy by the republican party, who are imbued with a considerable tincture of that scepticism which was generally allied with republican principles. The high church party endeavoured to remedy the deficiency of the establishment by sending sound missionaries, who were listened to by the people with enthusiastic delight. The author of "Four Years in France" mentions one who in departing from a city had his cassock torn off his back, and cut into pieces to be distributed as relics. The liberals deride them as ignorant fanatics; but some travellers, who cannot be charged with superstition, report them as displaying a good deal of natural eloquence, and that their doctrines appeared really very edifying, since many who had been guilty of thefts, even at remote periods, were induced by them to come forward and make confession and restitution.

2370. *The intellectual character* of the French has been brilliant, and since the age of Louis XIV. has had a powerful influence, in matters of taste, on the general literature of Europe: that prince, ambitious of glory in every form, extended a munificent patronage to letters and arts. The French Academy, though its endowments were not very splendid, and though intrigue often influenced its admissions, gave a fixed and high place in society to men of letters; who, amid all the frivolity of French character, were received even among the highest ranks with a distinction not accorded to them in any other modern country. The aim of Louis to make the French a sort of universal language was in a great measure successful; it became the established dialect at all the courts, and the chief medium by which the different nations communicated with each other. The departments in which the writers of that age excelled, were chiefly pulpit eloquence, poetry of a light and satirical character, and the drama in a somewhat fettered and artificial form. The writers of the following age took a bolder and more varied flight, and sought to turn the opinion of mankind into new channels upon all subjects. The wit and varied talent of Voltaire, the eloquence of Buffon and Rotisseau, the comprehensive views of Montesquieu, and the science of D'Alembert, gave a new turn to the ideas of the thinking world throughout Europe. These writers, with their successors of the same school, had a powerful influence in bringing on this revolution, in the ruins of which several of them were buried. Learning was for some time almost extinguished in France; but as soon as the revolutionary frenzy abated, the National Assembly constituted a new body called the National Institute, round which, under the changed appellations of Imperial and Royal, all the highest names in science have since continued to rally. The French during this period did not shine in poetry or general literature; but in mathematics, physics, and chemistry, the labours of Lavoisier, Laplace, Lalande, Chaptal, and a number of others, have, notwithstanding the powerful rivalry on this side the Channel, raised them perhaps to the very first place. Recently, however, France has produced some very eminent historians, and popular poets of a peculiar character; there has been also a remarkable extension of the habits of reading. The periodical sheets printed were in 1814 only 45,000; in 1826, they were 144,000. The most solid and useful branches also are those which have most increased, as appears from the following table, formed by M. Dupin:—

	1814.	1826.		1814.	1826.
Theology - - -	4,974,000	23,268,000	Military Subjects - -	441,000	1,445,000
Legislature - - -	1,374,000	18,605,000	Fine Arts - - -	773,000	1,999,000
Sciences - - -	2,546,000	12,160,000	Belles Lettres - - -	13,852,000	27,704,000
Philosophy - - -	753,000	3,032,000	History, Travels, &c. -	16,226,000	46,545,000
Political Economy -	1,634,000	2,097,000	Varieties, Almanacks, &c.	3,600,000	7,699,000

2371. *The literary and scientific collections* of Paris are the most splendid in Europe: the royal library contains 360,000 printed volumes, besides 70,000 manuscripts, and 5000 volumes of engravings. There are several other large libraries in Paris. The Museum of Natural History and the Jardin des Plantes are equally copious in their respective departments. All these are opened to the public in the most liberal manner. The provincial collections are also respectable, though they do not equal those of the minor princes of Germany; and France is, on the whole, less rich in this species of treasure.

2372. *Among the establishments for public education* in France, the universities, which are twenty-six in number, hold the first rank. That of Paris is perhaps the most celebrated in Europe, and was, even in the dark ages, the grand theatre of those dialectic combats, which then usurped the honours of science. Though destroyed during the fury of the Revolution, it has been re-established on a great scale, and with a larger appointment of professors than any other in Europe; it attracts students from every part of the kingdom, as none of the rest enjoy equal repute, and indeed bear at present only the name of academies. The *Lycées*, now called royal colleges, are an institution of Napoleon, and correspond nearly to our grammar schools, the expense of board and education being from 15*l.* to 30*l.* a year; but they enjoy a very unwarrantable monopoly of the right to teach Latin; they were attended, in 1825, by 10,000 pupils. Primary schools intended for the general instruction of the people

amounted in 1825 to 22,900, and were attended by, 116,000 scholars. Lancasterian schools have since been introduced, and amounted in 1820 to 800, attended by 80,000 scholars. M. Dupin remarks striking local differences in this respect. In the north, 13,000,000 of inhabitants send to school 740,000 children; while in the south, 18,000,000 send only 375,000: even in the south, the proportion is largest in the districts least favoured by nature, the Upper Alps and the Upper Pyrenees; while in Touraine, emphatically called the garden of France, it is only one in 229. All these establishments are under the patronage and control of the government, which does not, however, exhaust its finances upon them, since the whole amount in 1823 was not more than 95,000*l*.

2373. *The fine arts* were zealously promoted by the regent duke of Orleans, and by Louis XIV.; and though they never reached the splendour of the Italian or even of the Flemish schools, yet they could boast several masters of the first class; the Poussins and Claude Lorraine having fixed their residence and even found their scenery in Italy, became half Italian. Le Brun and Le Sueur were the chief artists decidedly French: of whom the former enjoyed the favour of the king, and the chief direction of the great works; but the latter has been pronounced by posterity to be his superior. After this, the French school sunk greatly, and was employed in delineating only the artificial forms of court society; but within the last thirty years a new school has sprung up, in which David, Gerard, Guerin, Girodet, and their followers have sought, not without success, to imitate the highest classical models. The French school has produced a series of very eminent engravers; and the names of Desnoyers, Bervic, and Massard still support its reputation, though it no longer surpasses, or perhaps equals, those of England and Italy. The French galleries of art have passed through many vicissitudes: before the revolution they were certainly the first out of Italy. During that convulsion, all the collections of the princes and nobles were put up to sale; the entire Orleans collection was brought over to England; the Crozat went to Russia; various minor collections shared the same fate. When the French, however, over-ran Italy and the Netherlands, they were seized with the desire of enriching Paris with treasures of art, and seized on whatever could be removed from among the masterpieces of the Flemish and Italian masters, and of ancient sculpture. Thus was assembled in the Louvre a display of all that is most brilliant in art, such as nothing before existing in the world could have rivalled. But a dire reverse awaited the nation. The allied armies who conquered at Waterloo, and thence advanced to occupy Paris, determined to exact full restitution of all this brilliant booty. The Venus, Apollo, and Transfiguration were sent off for Rome; the Descent from the Cross for Antwerp; and numberless other masterpieces were restored to their ancient possessors. The unseemly gaps thus left were filled up by native productions, and others taken from the palaces; and the gallery presents a *coup d'œil* almost as brilliant as ever; the intrinsic value, however, is vastly diminished; though since the purchase of the Borghese collection it still comprises some of the finest specimens of ancient sculpture.

2374. *The houses in France* under the former régime presented a great variety; for while the mansions of the nobles displayed a profuse splendour and luxury, and might be characterised as palaces, those of the body of the people, compared with the English, were very deficient in neatness and comfort; the rooms being dark, the passages straggling, the floors of stone, the doors and windows by no means well finished. The palaces, however, can no longer be maintained as such by their impoverished owners; and all the fine old châteaux throughout France are converted into barracks, prisons, or manufactories. On the other hand, the habitations of the peasantry, as well as their general condition, appear to be sensibly improved.

2375. *Amusement* used to form as it were the life of a Frenchman, and was sought for in every various and possible shape; but since the Revolution a very great change has taken place in this respect. Paris still claims to be, as it were, the centre of gaiety to the civilised world. The Parisians go from home in search of amusement much more than their neighbours; almost all their leisure is spent in places of public resort, which are open on terms that render them accessible to all classes. The attendance on the theatres is not occasional, as with us, but constant and habitual; and dancing is an exercise peculiarly French, in which, as to agility, and perhaps grace, they excel most nations. Much of their time is also spent in the open air; and the extensive ranges of gardens in Paris are provided with every recreation suited to the tastes of its citizens. Although many improprieties doubtless mingle with these entertainments, especially in Paris, there is less of intoxication, turbulence, or quarrelling, than in the amusements of the lower orders with us: so far, even, as concerns the public places, there are fewer open violations of decorum.

2376. *Dress* is a particular in which the French long claimed, and were allowed, to give the law to the rest of Europe. Paris has been for ages the grand *magasin des modes*. In that capital seems to have originated the system which is termed fashion, and which consists in the continual change, according to a prescribed model, of the form and construction of every part of the human attire. Such light and constant changes, however, while they indicate an inordinate attention to the object, seem as inconsistent with the formation of a pure and elegant taste, as the immutable costumes of our ancestors and of the East. The empire of Paris seems considerably shaken by the extinction of its brilliant societies, and its long separ-

ation by war from the other countries; but its influence remains still very considerable in this department.

2377. *In the preparation of food*, the French equally boast of a refinement and *recherche* superior to that of the other European nations. Instead of plain joints, presented in their natural form, French cookery delights in what are called made dishes, stews, fricassees, and ragoûts, which retain few traces of the original material. On the merits of this system various opinions have been entertained; but at present the fashion of this cookery out of France is on the decline, and the time seems past when it was considered a matter of state that the tables of the great should be covered with French dishes.

SECT. VII. Local Geography.

2378. *The local divisions of France*, prior to the Revolution, were provinces, thirty-two in number, most of which had formed independent states, and even little kingdoms, when they were merged into the mass of the French monarchy. The National Assembly, however, superseded this division by one much more minute, into departments; which has been retained by the Bourbons, and is the basis of all administrative operations. It is indeed very convenient, being founded upon natural divisions of rivers and mountains: all the departments are tolerably equal as to magnitude, and each has its seat of administration nearly in the centre. All the exclusive privileges and restraints upon internal communication, which were attached to the arrangement into provinces, have been happily removed. Yet these divisions must still be kept in view, not only because they are necessary for the understanding of history, but because they remain rooted in the mind of the nation, and often mark striking differences of race, of manners, and even of language. It would not consist with our limits, or be interesting to readers out of France, to enter into a detailed description of each department; but the following tables will exhibit a very comprehensive view of their respective statistical details. The first exhibits the departments in their relation to the ancient provinces, their extent according to the report of the commission of the Cadastre, their population according to the census of 1827, and their chief cities and towns. The square French league may be reduced to the square English mile by multiplying by 8, or, more closely, 7.84.

2379. *The following table* exhibits both the provinces and the departments as nearly as possible in their relation to each other, with their extent in square leagues, and the population of the capital and principal towns, according to the estimate formed by the French government in 1827: —

Provinces and Departments.		Square Leagues.	Population.	Cities and Towns, with their Population in 1827.	
Flanders	Nord	283	962,648	Lisle	69,860
Artois	Pas de Calais	338	648,969	Arras	22,173
Picardy	Somme	395	526,282	Amiens	42,032
Normandy	Lower Seine	300	688,295	Rouen	90,000
	Calvados	281	500,956	Caen	38,161
	Manche	304	611,206	St. Lo	8,509
	Orne	283	434,379	Alençon	14,071
	Eure	293	421,665	Evreux	9,729
Isle of France	Seine	24	1,013,373	Paris	890,531
	Seine and Oise	277	440,871	Versailles	29,791

						Carpentras -	9,756

2380. The following statistical table exhibits a comparative view of the state of culture and production in the different departments of France. The amounts of grain, cattle, and wool are furnished by Chaptal. The wine is drawn from the report presented to the peers by the Duc de Dodeauville, and the forests from the memorial of the sub-administrator, M. Herbin de Halle. The entire annual amount of land revenue is derived from an estimate of the average produce of the arpent in each department, founded upon the Cadastre or general survey of the kingdom. It is furnished by Chaptal:—

Departments.	Wheat.	Rye.	Oats.	Cattle.	Wool.	Wine.		Forests.	Land Revenue.
	Hectol.	Hectol.	Hectol.	No.	Kilo- grammes 2 1-5th lbs. each.	Hectoli- tres, 26½ gal- lons each.	Average Prices in Francs.	Hectares.	Francs.
Ain	374,000	498,000	148,000	93,000	68,000	373,000	15	64,000	10,062,000
Aisne	1,422,200	1,040,000	566,000	84,000	1,107,000	291,000	22	103,000	27,441,000
Allier	282,000	746,000	1,721,000	111,000	147,000	288,000	17	106,000	8,238,000
Alps, Upper	180,000	166,000	13,000	25,000	338,000	101,000	16	74,000	3,604,000
—, Lower	185,000	108,000	786,000	11,000	556,000	99,000	16	60,000	4,654,000
Ardèche	108,000	394,000	39,000	54,000	384,000	77,000	18	28,000	11,767,000
Ardennes	663,000	458,000	2,000	80,000	557,000	55,000	20	150,000	12,203,000
Arriège	162,000	189,000	224,060	54,000	222,000	117,000	15	55,000	11,618,000

2381. *The Isle of France*, now divided into several departments, claims priority of notice as containing the capital. It is not, strictly speaking, an island; but being situated near the junction of the Oise, the Marne, the Aisne, and the Seine, is intersected by very numerous river channels. It is in general level, fertile, and highly cultivated; and beneath the surface are quarries of gypsum so copious, that the substance is commonly designated "plaster of Paris."

2382. *Paris*, the capital of France, has also made pretensions to be considered as the general capital of the civilised world. London can, in fact, alone dispute its claim, being more extensive, more wealthy, and the seat of a much more extended commerce; yet the

central situation of Paris, the peculiar attractions rendering it the crowded resort of strangers, and its brilliant and polished society, especially under the old monarchy, gave to this city a gayer aspect, and rendered it a more conspicuous object in the eyes of Europe. Paris is not only less populous than London, but in proportion to its population it covers less ground. It forms on both banks of the Seine an ellipse of about four miles in length and three in breadth. The principal streets are long, narrow, bordered by high houses, which, like those of Edinburgh, are each occupied by several families. The streets of shops are further encumbered by the exhibition of the merchandise in front of the doors, a practice only tolerated in the most obscure districts of British cities. Paris thus presents generally a more gloomy and confused aspect than London; nor has it any structure which can match the grandeur of St. Paul's, or perhaps the beauty of Westminster Abbey; yet some of its quarters contain long ranges of superb and stately edifices, which London cannot rival. The palaces of Paris, in particular, far excel those of the rival metropolis. The most distinguished is the Louvre, finished with the utmost splendour in the style that distinguished the age of Louis XIV. Its front, 525 feet long, is a model of symmetry, the effect of which is only injured by the want of space before it. The Louvre is not now occupied as a palace, but as a grand *depôt* of the objects of taste and art. The gallery, which is more than a quarter of a mile long, and the walls of which are entirely crowded with paintings that are still fine, forms a magnificent *coup d'œil*. The hall of statues is still adorned with some of the finest specimens of ancient sculpture. The Tuileries, which is

the present royal residence, was begun at an earlier period than the Louvre, and carried on at successive times; whence it exhibits varied and sometimes discordant features, but is on the whole a noble and venerable edifice, surrounded with fine gardens and avenues. The palace of the Luxembourg (*fig. 237.*), on the south of Paris, and the Palais Bourbon on the west, are edifices of great taste and beauty. The former, now

THE LUXEMBOURG.

stripped of the famous series of paintings by Rubens, which has been transferred to the Louvre gallery, affords in one part a place of assembly for the Chamber of Peers, and in another apartments for the exhibition of paintings by living artists; while the Palais Bourbon is in part occupied by the Chamber of Deputies. The Palais Royal (*fig. 238.*) is no longer exclusively a palace, but is in part

PALAIS ROYAL.

leased out to sundry persons, for purposes partly of business, but much more of pleasure: it is filled with shops, coffee-houses, taverns, gaming-tables, and every form of gaiety and dissipation which can find acceptance in such a city. Notre Dame, the ancient cathedral of Paris, is somewhat heavy and massive, but the interior is richly decorated. The modern church of St. Génévieve, called during the Revolution the Pantheon, was highly extolled during its erection, as destined to eclipse both St. Peter's and St. Paul's; and such was the expectation entertained in France, till, the scaffolding being removed and the front thrown open,

its inferiority became apparent: however, it is still an edifice of a high class (*fig. 239.*). St. Sulpice is also a modern structure. Paris has no fine streets, nor any of those ample squares which are so great an ornament of London. It boasts, however, of its *places*, which, without having the regular form or dimensions of a square, command admiration by the ranges of noble buildings that surround them. In particular, the *Place Louis Quinze*, standing in a central situation among the

CHURCH OF ST. GENEVIEVE.

palaces, presents one of the most brilliant points of view to be found in any city. This capital possesses also great advantages in the wide ornamented open spaces which lie in the very heart of the city. The Boulevards, the ancient rampart of Paris, when it was circumscribed within a much narrower compass, are now converted into a walk adorned with rows of trees, and filled with numerous exhibitors and venders of every thing that can conduce to public amusement. The gardens of the Tuileries, and the embellished spot called the *Champs Elysées*, are also open to the public.

2383. *The statistics of Paris* have been carefully illustrated in a series of interesting works by the Count de Chabrol. The population, in 1821, amounted to 713,966, but has now risen to 890,431. The births, in the three years ended 1821, averaged 24,700; the deaths 22,680; leaving thus 2000 as the annual excess of births. A third of all the births were illegitimate, and of these only a third were acknowledged by the parents. The still-born children were averaged 1365. The average of marriages in the three years was about 6000. In the three years 732 died of small-pox, and only one child out of twenty-five was vaccinated. The violent deaths averaged 350, half of whom were married persons, and the most common cause was domestic chagrin. Drowning was the most frequent mode: 170 persons were drowned annually by accident. The consumption of Paris consisted, in 1823, of 76,689 oxen; 8142 cows; 74,759 calves; 361,946 sheep. The taxes paid in Paris amount to 3,150,000*l.*, which is 4*l.* 6*s.* for each inhabitant; while the rest of France pays only at the rate of 1*l.* 2*s.* 6*d.* House rent amounts to 2,500,000*l.*; being 3*l.* 15*s.* for each inhabitant. The number of houses, in 1821, was 27,000, with an average of thirty-four doors and windows in each. There is an average of 209 bankruptcies, the amount of which, in 1819, was between 250,000*l.* and 300,000*l.* The loans made on pledges by the charitable establishment called the *Mont de Piété* were 750,000*l.*, upon 1,000,000 articles, of which 540,000*l.* was redeemed. There are fourteen hospitals for the sick, and eight *hospices* for the infirm. The former received annually 42,500, of whom about 40,000 went out cured; the latter 18,500. The annual expense is about 280,000*l.* There is besides an office of charity in each of the twelve *arrondissemens*, the aids of which are administered by "sisters of charity," who divide the poor among themselves, make regular lists of them, and pay frequent visits. They make an annual collection in their district, the produce of which is transmitted to the office. The annual distributions made by the offices of charity amount to 50,000*l.* in money; 747,000 quartern loaves; 270,000 lbs. meat; 19,000 ells of cloth, &c. The manufactures of Paris are considerable. The principal are of works in gold and silver, which employ 7000 or 8000 workmen, and yield a value, according to M. Dupin, above 5,000,000*l.* sterling. There are manufactured also, by 2000 workmen, 80,000 gold and 40,000 silver watches, with 15,000 clocks, which may be worth 750,000*l.* Sugar refinery is also supposed to produce 20,000,000 lbs., worth 1,300,000*l.* There were eighty printing-offices, employing 600 presses and 3000 workmen, and using annually 280,000 reams of paper; supposed value, 350,000*l.* Of the various articles above enumerated there are exported to the value of nearly 2,000,000*l.* sterling. Paris is visited by 12,000 or 13,000 boats, of which 1000 from the lower Seine, and the rest from the upper. Twenty are steam-boats. The city has 1000 boats of its own.

2384. *The environs of Paris* are not covered with those numerous villas and country residences which have been constructed to gratify the rural taste of the citizens of London. Immediately beyond the gates they present a flat open corn country. They are chiefly marked by the royal palaces; superb fabrics, the works of successive kings, and on which millions have been expended. The most elaborate and most splendid is Versailles (*fig. 240.*). It

240

CHATEAU AT VERSAILLES.

was begun by Louis XIII. who found it little more than a village; but its chief ornaments are due to Louis XIV., who, during twelve years, expended immense sums in surrounding it with every kind of magnificence. The front is highly elegant, built of polished stone, and approached by three great avenues. The interior consists of spacious apartments embellished in the most costly manner, and many parts of them, and of the staircases are covered with frescoes executed by eminent French painters. The interior and the gardens are filled with crowds of statues, partly antique and partly the work of French sculptors. Water was at first deficient; but it has been conveyed in such abundance as to be lavished in fanciful and fantastic forms, — fountains,

jets d'eau, cascades, with which Versailles is more profusely embellished than any other royal residence. The two palaces, called the Great and Little Trianon, are in the vicinity, and are celebrated, particularly the last, for gardens laid out in the English style. The long residence of the court at Versailles assembled round it a splendid city formed by the courtiers and great nobles, who considered it necessary to have at least a mansion there. Since the tragic scenes of October, 1789, the palace has never been inhabited; though the Bourbons, after their return, placed it in repair. Hence the city has declined in population, and the late mansions of the nobles are in a great measure occupied by English residents. St. Cloud, four or five miles distant from Paris, is particularly admired for its gardens and extensive woods, an excursion to which forms a popular amusement, especially on festival days. It was the favourite residence of Napoleon, whose court was thence called the cabinet of St. Cloud. Fontainebleau is the hunting-seat of the monarchy, being surrounded by a forest of nearly 30,000 acres. The palace, built by successive monarchs, from Francis I. to Louis XV., is chiefly noted for its long and numerous galleries. Among the few towns in this country, Meaux is distinguished not only by the beautiful choir of its cathedral, but by having been the see of the celebrated Bossuet, whose tomb it contains. Melun is a considerable, but ill-built and gloomy, old town.

2385. *The northern departments*, comprising the provinces of French Flanders, Picardy, and Normandy, compose together an extensive plain, the richest, most flourishing, and most highly cultivated in the kingdom. The farms, though of various size, are generally larger than in the rest of France; the improved English processes are gaining ground, and the introduction of artificial grasses has in a great measure supplanted the routine of wheat, oats, and fallow. This region is also the chief seat of manufactures. These provinces have produced many men of distinguished talent, and knowledge is very generally diffused in them. The Flemings retain their national character, distinct from that of the French; heavy, phlegmatic, industrious, addicted to pretty close drinking and long rustic festivals. The Norman still partakes the adventurous spirit of his forefathers; he loves expeditions and journeys, readily engages in any enterprise, and eagerly pursues it.

2386. *The cities throughout all this part of France* are large and flourishing. Those of French Flanders, or the *Nord*, rank among the strongest fortresses in Europe, and are the bulwarks of the monarchy. Lille perhaps holds among these the very first place, being considered the master-piece of Vauban. It was reduced by Marlborough only after a long blockade, and is considered in any other way almost impregnable. It is also well and regularly built, and the *Rue Royale* is a very splendid street. Lille has also a very considerable variety both of manufacturing and commercial industry, with institutions both for literature and the arts. Douay is an ancient and strong town on the Scarpe, and enjoys some celebrity as a seat of rather antiquated and scholastic learning. Its university consists of three colleges, now united, one of which is called the English college, and is resorted to from all the three kingdoms as a place of catholic education. Cambrai is a very ancient and celebrated city, the capital of the Nervii in Cæsar's time, and afterwards of the kingdom of the Franks. Here was concluded, in 1597, the league of Cambrai, which caused the downfall of Venice; and it was the scene of other important diplomatic transactions; but perhaps the name is best known from its having formed the archiepiscopal see of Fénélon. It ranks still as a

fortress of the first class, and was one of those held by the army of occupation, after the peace of Paris, in 1815. Valenciennes is another ancient bulwark of the kingdom, which yielded to the allies in 1793, after a long siege; but they did not derive any advantage from their success. It has some fine manufactures of lace, gauze, and cambric.

2387. *In Picardy and the part of the Isle of France bordering on it*, there are several large and flourishing cities. Amiens has long been celebrated for its manufacture of coarse woollens, as serges, plush, velvets for furniture, and carpets; also coarse linens. Here was concluded the peace of 1801, between Britain and France. Its cathedral (*fig. 241.*) is one of the most spacious and most highly ornamented in France or in Europe. Abbeville is celebrated as one of the few seats of the manufacture of very fine woollen cloth, which surpasses even the English; it deals most extensively in sailcloth, sheeting, and other coarse fabrics from hemp and flax. St. Quentin, the scene of the great victory of Philip II., enjoys a more humble and useful

241

AMIENS CATHEDRAL.

distinction as one of the most thriving manufacturing places of France. Its manufactures consist in lawns, cambrics, and still more of late in the spinning and weaving of cotton; all which employ in the town and neighbourhood upwards of 50,000 persons. The citizens of St. Quentin display an enterprise and an activity in pushing every new and promising branch of industry, which is not usual in France. A canal is here cut from the Oise to that of Douay, remarkable for its extensive tunnels. Laon is an ancient town, with a stately cathedral. Soissons is distinguished in French history, and its bishop had, second to that of Rheims, the right of crowning the king of France. It does not now present any striking features. Beauvais is thriving and industrious.

2388. *The ports of Picardy and French Flanders* are also very deserving of notice. Dunkirk, being the only one which opens into the North Sea, was always considered of great importance. Louis XIV. having definitively obtained this place in 1662, made it one of the strongest harbours in Europe. It soon became so annoying to British trade, that advantage was taken of the triumphs of the war of succession, to require, at the treaty of Utrecht, its entire demolition. By canals and other means, the French contrived always to replace it in an effective state; but by successive treaties, the demolition of the fortifications on the side of the sea was again and again stipulated, till the circumstances of the peace of 1783 obliged England to cease from exacting it. From that time Dunkirk became the main centre of the privateering system. It has also a considerable share of fishery and of the Baltic trade. A memorable era in its history was its siege by the British in 1793. They were compelled abruptly to raise it, and this formed the commencement of a long series of reverses sustained by the allied arms. Dunkirk has a good harbour in the centre of the city, entered by a canal of a mile and a half; it is rather well built, but for want of springs the inhabitants are obliged to use rain water. The neighbouring territory is low and marshy, only preserved from the inundation of the sea by a ridge of downs, and only cultivated by means of numerous draining canals. Calais is well known as the point of communication with England, which so long held it as the key of France, even after her

aims at the entire conquest of that monarchy had ceased. At present, it is chiefly supported by the packet intercourse, its indifferent harbour (*fig. 242.*) unfitting it for any commerce on a great scale. Calais is in a very flat country, intersected by canals, by which it might be even inundated. Boulogne has more maritime importance; though its port, choked with sand, will no longer receive vessels of any size, unless at high tide. It has lost altogether the forced consequence given to it by the

CALAIS HARBOUR.

construction of the grand flotilla, destined it subdue the British empire, but now abandoned to rot. Its proximity, however, to our coast has rendered it a great resort of English families, who inhabit it to the amount of several thousands. The fishery of herring, mackerel, &c. varies in value from 40,000*l.* to 80,000*l.*

2389. *The cities of Normandy* are larger and more important than those already described. Rouen is one of the noblest in France. Its manufacturers are, perhaps, the most enterprising and industrious in the kingdom, and from their vicinity to England have had peculiar facilities in borrowing her processes. The main staple is cotton-spinning and weaving, which is supposed to occupy two thirds of the 55,000 workmen, and so to constitute the same proportion of the two millions sterling of manufactured goods annually produced. The cathedral (*fig. 243.*), commenced by William the Conqueror, was considered one of the finest specimens of ecclesiastical architecture in France, till the late disaster, which overthrew a great part of it. The streets are excessively narrow and dirty, though those adjoining to the Seine are agreeable. That river was long crossed only by a pontoon, composed

ROUEN CATHEDRAL.

of nineteen large barges, strongly moored together by iron chains; but as this had many inconveniences, a handsome stone bridge has been lately substituted. At Elbœuf, near Rouen, is a manufactory of fine cloth, almost equal to that of Louviers. Caen is a very ancient city, of great historical name, the favourite residence of William the Conqueror, and the frequent head-quarters of the English armies. It is still a considerable place, rather unusually well built for a French town, containing a handsome castle, the only remaining part of its fortifications, and some fine old churches. Its manufactures are numerous, but none of them very eminent, except that of lace, which gives employment to about 20,000 females in this place and the neighbourhood. It is of some eminence as a seat of literature, gave birth to Malherbe and Huet, and has a university of considerable reputation, which, though suppressed during the Revolution, has been restored in full lustre. Havre, at the mouth of the Seine, is the port of Paris, and one of the most active seats of French commerce. The custom duties, in 1824, amounted to somewhat above a million sterling, and its trade has since been greatly augmented. The chief fabric of the town and neighbourhood is that of printed cottons. It is a gloomy town, the streets narrow, and the houses often built of a framework of wood filled up with mortar. Dieppe, St. Valery, Fécamp, and Honfleur are very active stations for fishing; which is not, however, carried on with the same energy and adventure as before the Revolution. The immense efforts made to render Cherbourg a naval station of the first rank, have proved nearly abortive. The French government, after the peace of 1783, began to erect a series of cones, with the view of breaking the force of the waves; but these were overwhelmed, and retain no vestige of their original form: they lie under water, a shapeless ruin, which Bonaparte in vain attempted to make the foundation of a regular breakwater. After two millions had been spent in this undertaking, he employed other five millions in forming an interior basin and a wet dock; but all these mighty works remain unfinished.

2390. *Britany* forms a peninsula distinguished by many marked features from the rest of France: its rude surface, composed in a great measure of forests, marshes, and heaths, enabled it not only to preserve a large portion of its original Celtic population, but to give shelter to fugitives from Britain, whence it received its name. After being long a separate duchy, it was united to France by the marriage of its heiress with Louis XII. It retained, however, down to the era of the Revolution, its feudal states, which assembled every two years. The Bas Breton is a Celtic dialect. The people are very numerous and very poor. The country is divided into small properties or farms, seldom exceeding twelve acres, cultivated by the manual labour of the occupants, according to antiquated and unskilful processes, to which they adhere with the most fixed determination. The peasantry reside in small huts, gloomy, dark, and damp; they are strongly attached to their homes; ignorant and superstitious, but at the same time frank, brave, hospitable, constant in their friendships, and faithful to their word. They are stubborn and hardy, and those on the coast make bold sailors.

2391. *Of the cities of Britany*, Rennes, the ancient capital of the Rhedones, is the first in dignity, and was the place of meeting for the states, the discontinuance of which has diminished its importance. It is still rather a fine and handsome city, having been regularly rebuilt since a great fire in 1720; and its cathedral of St. Peter is adorned with lofty towers. There is a library of 30,000 volumes, a fine botanic garden, a museum of natural history, and extensive collections in the fine arts. It carries on some trade by the river Vilaine, which admits barges of considerable size. Vannes, the ancient capital of the Veneti, is a much smaller and poorer town, though its vicinity to the sea gives it some commerce and fishery. Morlaix and Quimper are rather good towns in the eastern departments: but the finest city in Britany is undoubtedly Nantes, which seems almost to belong to the rich provinces on the Loire; it is situated on a hill above that river, twenty-seven miles from its mouth, and has the advantage of delightful walks and environs. Its situation, at the mouth of the greatest river in France, is very favourable to commerce, which was carried on to a vast extent, till ruined by the disastrous influence of Napoleon's continental system; but Nantes is beginning again to rear its head. The West India trade and the cod fishery were the most extensive branches. Much ship-building is carried on for the merchant service, and vessels of 1000 tons are occasionally built. Its manufactures are various, and were formerly extensive, especially sugar refinery, cotton, woollen, and linen cloths, and earthenware. It is connected with the opposite side of the river by a noble bridge, which, uniting five different islands, extends in its entire length more than two miles. In its construction Nantes exhibits the usual faults of old cities; the most agreeable parts are the suburbs, and the islands thickly planted with trees and houses.

2392. *Brest*, on the western coast of Britany, is the chief naval station of France on the ocean, as Toulon is on the Mediterranean. It was selected for this purpose in 1631 by Cardinal Richelieu, in consideration of its harbour, which is secure from every wind, and of a spacious roadstead, affording anchorage to 500 ships of war. From Brest issued the fleet which was totally defeated, in 1792, by Lord Howe; and during the whole of the subsequent war between England and France, this port, with the navy which it contained, was held in almost constant blockade. The works of Brest are very strong, and the attempt made in

1694 to carry them by storm, was repulsed with considerable disaster. The town, though modern, having been built in haste, and with a sole view to utility, is crowded and dirty; but within the last half century there has been built a handsome suburb, called *La Recouvrance*. Brest, besides its naval importance, carries on a considerable fishery.

2393. *There are other maritime stations* of considerable magnitude in Britany. L'Orient has been made a depôt for naval stores, and strongly fortified: it derived much importance from being the almost exclusive seat of the commerce of the East India Company; but since that trade has been nearly annihilated, this port has greatly declined. St. Malo contains a race of bold and hardy mariners, actively employed in the Newfoundland and other fisheries; and who, in time of war, exercised briskly the trade of privateering. Morlaix carries on a considerable trade with the north of Europe. Quimper, though ranking above Brest, as capital of the department of Finisterre, is now only an old town of little importance.

2394. *The provinces on the Loire*, in its course from east to west, comprehending Orleannois, Touraine, Anjou, to which may be added those of Maine and Perche, adjoining on the north, are the most central and perhaps the richest in the kingdom. A great part, indeed, especially of Anjou and Maine, is covered with those wide wastes, overgrown with brush-wood and heath, which occupy so much of the French soil. But the banks of the Loire around Orleans are generally considered the garden of France; they consist of unbounded plains, through which the magnificent Loire winds its stately course, and which are variegated with rich meadows, vineyards, gardens, and forests. On this theatre were acted many of the greatest events in the history of the monarchy, particularly its rise from the apparent peril of total subjection, through the inspiring influence of Joan the Maid of Orleans.

2395. *The cities of this region* are celebrated and magnificent. Orleans, in former times, ranked almost as a second capital: though it exhibits the usual characters of antiquity, it is a superb and beautiful city. A very fine stone bridge of nine arches opens to the *rue royale*, spacious and handsome, which extends to the fine square in the centre: here is placed a statue of Joan, the sculpture of which is not altogether so elegant as might be desired. The cathedral is a very fine edifice, the choir of which was raised by Henry IV. From its steeple is an almost unbounded view over the magnificent plain of the Loire. Situated in the centre of France, and dividing as it were the Lower from the Upper Loire, Orleans enjoys a great transit trade. Blois is almost equal to Orleans in historical celebrity; its ancient edifices, placed on a hill above the Loire, have a most commanding appearance. The castle, on a rock overhanging the river, is an immense and lofty pile, full of windows of all shapes and sizes, balconies, galleries, buttresses, and "a strange incongruous assemblage of buildings destined for ornament in peace and defence in war." All the parts are little; but the whole is so vast as to be almost sublime. In this edifice the states-general once assembled. The glory of Blois has now entirely passed away; its streets are narrow, gloomy, and dismally dirty. Tours, equally ancient, is now much more flourishing; its plain is pre-eminent, even among the other districts on the banks of the Loire. The silk manufacture, first introduced here, has been in a great measure transferred to Lyons, but it still employs 7000 or 8000 persons. Happily for the beauty of the city, a great part of it was consumed 50 years ago, and occasion was taken to build a new street, running its whole length, of fine hewn stone, broad, and on an elegant design; it is, perhaps, the finest in France. It is connected with a bridge of 14 arches, which till of late was considered equally unrivalled; and also with a fine promenade bordered with trees. The metropolitan church was almost entirely demolished during the revolutionary excesses; only two of its lofty spires remain. The beauty and abundance of the country around Tours has attracted such numbers of English residents, that Mrs. Carey was asked on the road what great convulsion was agitating England, that her people were flying from it in such crowds. Saumur, once highly flourishing and industrious, lost two thirds of its population by the revocation of the edict of Nantes. Angers is a large, old, steep, ill-built town, but has a considerable trade; its monuments have been dreadfully shattered during the Revolution. Le Mans, capital of Maine, on the Sarthe, is very old, but large and clean, with a spacious market-place, and some considerable manufactures.

2396. *The provinces between the Loire and the Garonne*, Poitou, Berri, Limousin, and the Marche, are of diversified and somewhat peculiar aspect: they present none of those boundless plains which characterise France north of the Loire; they are every where traversed by valleys and ridges of hills, never rising into mountains, but giving to the country a broken and variegated aspect. This, according to the nature of the soil, is sometimes rude and dreary, sometimes gay and smiling. Mr. Young ranks the Limousin as the most beautiful district in all France, such is the variety of hills, dales, streams and woods which compose its landscape. Mrs. Carey describes Marche, beyond Argenton, as singularly pastoral; the hills covered with sheep, goats, kids, and lambs, the last of which at evening come down bleating, and are received into the houses. Poitou, a part of which is so fatally celebrated under its new name of La Vendée, is a rough country, a great part of which is covered with a forest called the Bocage. All these districts are more productive of cattle

than of grain, though they are cultivated by a simple peasantry with hardihood and vigour, but quite in the antique style, and with a strong antipathy to all modern improvements. In Poitou, the proprietors, being small, and residing much on their estates, excited feudal feelings and attachments, that were extinct in the rest of France; hence the formidable war which they waged single-handed in defence of the ancient régime.

2397. *The cities in this range of provinces*, though ancient, are neither large, nor distinguished by much industry. Poitiers is of high antiquity, and presents some interesting Roman remains; in modern times it is distinguished by the signal victory gained here by the Black Prince. The city is of great extent, but comprises many empty spaces and gardens. Limoges is an ill-built town, with many houses of timber, roofed with tiles, and projecting eaves, but there are several handsome squares and fountains, and the public walks command a beautiful view of the Vienne flowing down a charming valley. Its cathedral, said to have been built by the English during their temporary possession of this part of France, suffered much during the revolution, and has only one tower left standing. Bourges, the ancient Biturigæ, is very ill built, but adorned with a fine cathedral, and distinguished for its university, and as the birth-place of Bourdaloue, and of the jesuit, Father d'Orléans. Châteauroux is gloomy, but has a large woollen manufacture.

2398. *The two departments of the Charente*, watered by the fine river of that name, form a region different in character from those now described; level, and extremely fertile, though in some parts marshy and unhealthful. A great part of the produce of its rich vineyards is at Cognac converted into brandy, which bears an unrivalled reputation, though, probably, the name is applied with a fraudulent latitude to inferior liquors. The yellow tinge so generally given to brandy is the consequence of a local custom at Cognac. Saintes is ancient even as a French city. An ample theatre, an aqueduct, and a triumphal arch of white marble, attest its ancient importance as a Roman city; and the cathedral is said to belong to the age of Charlemagne. But the most conspicuous features of the Charente are Rochelle and Rochefort. The former is renowned as the grand and last bulwark of the protestant cause, and its reduction, effected by the almost incredible efforts of Cardinal Richelieu, fixed the downfall of civil and religious liberty in France. Though no longer a haven of the first magnitude, its colonial trade, prior at least to the late war, was very considerable. The town is handsome, with broad streets, many of the houses built on arcades, with shops beneath, as in Chester. Rochefort has little trade, but is one of the principal French naval stations. It has a secure harbour, with very safe and extensive docks. Being one of the few towns in France that are not much more than a century and a half old, it is built on a regular plan, with broad open streets. Angoulême, in the interior, stands on a rock in the centre of a charming valley, through which winds the silver stream of the Charente. It is a clean well-built town, having a cathedral with five cupolas, and displaying other marks of historical importance. There is a large manufacture of paper.

2399. *Guienne* is a most important province, which for several ages formed an appanage of the English crown. It consists of a magnificent and highly cultivated plain, watered by the Garonne, whose broad stream here resembles an arm of the sea, and by its ample tributaries, the Tarn, the Lot, and the Dordogne. It is distinguished by various rich productions, but more especially by the wines bearing the name of claret, which though not quite so rich and highly flavoured as some, are so light and agreeable that a greater quantity is drunk at the tables of the opulent, than of any other. M. Frank, in a late work published at Bordeaux, estimates the entire produce of claret at 250,000 tuns. The wines of the farms Laffitte and Château-Margaux are the most esteemed; but much is sold under these names which has no title to them.

2400. *Bordeaux* (*fig. 244.*), near the mouth of the Garonne, is one of the grandest

BORDEAUX.

emporia in France, and, indeed, in Europe. Situated at the mouth of the Garonne, which here allows the largest vessels to ascend to its port, it exports all the valuable produce of this great southern plain, of which the wines are said to amount to 100,000, and brandy to 20,000 pipes annually. It is engaged also in colonial trade, and in the cod and whale fisheries. Recent travellers remark a

greater display of wealth and prosperity in this than in any other of the French commercial cities. Every thing is on

a grand scale, and buildings are in progress which, when finished, will leave it without a rival in France. The theatre, designed after that of Milan, is considered a model of architectural beauty. Many of the ecclesiastical structures were founded by the English. A very republican spirit is said to prevail at Bordeaux.

2401. *The other towns of Guienne are not of the first magnitude.* Montauban embraced with ardour the protestant cause, and had a distinguished university, which was suppressed, when the place was taken in 1629, by Louis XIII., and the fortifications razed. This seminary, however, was restored by Napoleon in 1810. Montauban, is well built, of painted brick, with wide and clean streets; and an elevated walk, which commands a most extensive view, reaching to the Pyrenees. Agen is a very dirty ill-built town, but famous for the plums raised in its vicinity. Cahors has some thriving manufactures, and its vicinity produces the *vin de Grave*, which is held in high estimation. Rhodéz, on the Aveyron, is a gloomy old town, but the seat of a distinguished bishopric.

2402. *Gascony* is a large province, extending to the Pyrenees, and consisting chiefly of a wide level surface, of peculiar character, called the *landes*. These are plains of sand, in some places loose and blowing, but mostly covered with pine trees, sometimes affording pasturage for sheep, and more rarely detached tracts fit for cultivation. The Gascons, long an independent people under their dukes, are a peculiar race, fiery, ardent, impetuous, and proverbially addicted to boasting; hence the term *gasconade*. Bayonne, though not very large, is one of the strongest and prettiest towns in France. Situated at the broad mouth of the Adour, it has a considerable traffic in exporting the timber of the Pyrenees and the Landes, and sends also vessels to the cod and whale fisheries. Mont de Marsan, the capital of the Landes, is but a small and poor place.

2403. *The Pyrenean departments* comprehend some interesting features. Bearn, the little original principality of Henry IV., which he governed with paternal kindness; and Roussillon, which underwent several revolutions, alternately belonging to France and to Spain, before it was finally annexed to the former. Young gives a delightful view of the state of this mountain district. It is divided into a number of small properties, which are well enclosed, well cultivated, each comfortable cottage being surrounded by its garden well stocked with fruit trees; the inhabitants snugly dressed, like Highlanders, in red caps. The subdivision of property, though great, seems not to have gone so far as to lead to misery. Pau is a considerable town, in a romantic situation, and celebrated as the birth-place of Henry IV., whose cradle is still shown in the ancient palace, now converted into a prison. It makes a good deal of linen, and is noted for its excellent hams, which are exported from Bayonne. Tarbes, capital of the upper Pyrenees, and Bagnères, with its mineral hot springs, a place of crowded and fashionable resort, are delightfully situated, affording an approach to the fine valleys of the highest Pyrenees. The slopes of the neighbouring mountains are richly cultivated, and often well enclosed. Roussillon is Spanish as to language and customs; but the magnificent roads effected in defiance of natural obstacles, and the thriving industry of the people, mark the influence of a more active and enlightened government. The extensive fortifications of Perpignan render it a barrier of the kingdom. It is gloomy and ill built, but has some manufactures.

2404. *Languedoc*, the ancient Gallia Narbonensis, and afterwards the domain of the counts of Toulouse, is the pride of France in regard to climate, soil, and scenery. The air along its coasts is generally considered the most salubrious in Europe. The plains of Languedoc are celebrated; yet they are encroached upon not only by the Pyrenees on the east, but by the Cevennes, which form their constant northern boundary, and in many places reduce them to a breadth of a few miles. But on the line from Beziers by Montpellier to Nismes, the plain is of much greater breadth, and displays a luxuriant fertility scarcely rivalled in any other part even of this happy region. Every thing flourishes here, even what is most strictly denied to other provinces; not only grain and the vine, but the silk-worm and the olive.

2405. *The cities of Languedoc* are not of the very first magnitude; but they are handsome and finely situated; and they present some interesting Roman monuments. Toulouse covers a great extent of ground, but it has suffered in consequence of the discontinuance of its parliament, which was one of the most important in France. The cathedral is very large, but not very beautiful; and many of the churches were destroyed during the Revolution. There is an university attended by 1500 students, and two large libraries open to the public. Castres is a well-built, industrious, large town, the birth-place of Rapin and Madame Dacier. Carcassonne still retains some of the bastions and towers of the castle on its hill; but this ancient quarter is almost deserted in favour of the neat pleasant town built beneath. Beziers is ugly and dirty, but has a handsome cathedral, and is important from its site on the canal of Languedoc. Narbonne, though celebrated as a Roman capital, presents few monuments of that people; these are said to have been taken down at the building of the walls. Montpellier enjoys an unrivalled fame for its mild and salubrious air; but our late travellers, Mr. Matthews and Mrs. Carey, have declared themselves unable to discover on what that re-

noun is founded. It is subject to alternations of heat and cold; cloth pelisses must be worn the whole winter, and fires cannot be discontinued till May. It is, however, an agreeable residence; the public walk commands a view over the Mediterranean and the surrounding country, scarcely equalled in Europe: there is a flourishing medical school, with good practitioners, and a library of 40,000 volumes. Montpellier is not uniformly well built; but it presents a noble Roman aqueduct, a fine cathedral, and other public buildings. Nîmes is one of the greatest and most flourishing cities in the south of France. The silk manufacture, as already noticed, flourishes there to a great extent. More than half the inhabitants are protestant, who, as may be well remembered, were, on the restoration of the Bourbons, exposed to violent outrages on the part of their catholic fellow citizens. The catholic author of "Four Years in France" alleges that the protestants had somewhat too freely used their superiority during the revolution; but these disorders were disavowed by the French court, and have ceased. The city is ill built, ill paved, ill laid out; but there is a fine boulevard bordered with trees; and it is particularly illustrious for the magnificence of its Roman monuments. The amphitheatre is nearly entire, and, though rather smaller than that of Verona, from its massive grandeur, and the enormous stones of which it is constructed, suggests the idea of an imperishable fabric. But the edifice called the *Maison carrée*, supposed to have been a temple of Augustus, is that which has excited the admiration of all travellers, from its extreme elegance and graceful proportions, which render it almost a perfect model of architectural beauty. It remains after so many ages quite entire, "as if savage and saint had been alike awed by its superlative beauty." Near Nîmes is the Pont du Garde (*fig. 245.*), an ancient bridge, or rather

PONT DU GARDE.

aqueduct, forming one of the most remarkable monuments now extant of Roman grandeur.

2406. *Provence* is one of the most celebrated and interesting of the French provinces, first, as the earliest seat of wealth, civilisation, and poetry; next, as containing the ecclesiastical capital, Avignon, near which is Vaucluse, the favourite residence of Petrarch; lastly, as in-

cluding Toulon and Marseilles, the greatest naval and the greatest commercial city in the kingdom. The classic stream of the Durance, though it crosses the whole region from its alpine boundary to the Rhone, and too often overflows its banks, does not preserve the extensive tracts covered with rude calcareous hills from the evils of aridity. Although, therefore, the products of this province are various, and many of them fine, it does not yield corn sufficient for its own consumption, nor can it boast of extensive manufactures, but depends chiefly upon commerce.

2407. *The cities of Provence* rank, in all respects, among the greatest and most interesting of the kingdom. Aix is not the largest, but is reckoned the capital, and was formerly the seat of the parliaments of Provence. Its name is contracted from that of *Aquæ Sextiæ*, given to it by the Romans from the copious warm baths, in whose vicinity numerous medals and inscriptions have been discovered. It is pleasant, airy, well built, in a fine plain encircled by lofty mountains. The *cours* is very beautiful, formed by two rows of trees, with hot fountains bubbling up, at which women are seen washing clothes. Greater celebrity attaches to the name of Avignon, for some time an ecclesiastical capital, and still more illustrious by association with the names of Laura and Petrarch. It is finely situated on the Rhone, with many handsome houses; but the streets are crowded and ill paved. In the centre rises an insulated rock, separated by the river from a range of hills on the other side, and in which are the remains of the palace of the popes, now converted into barracks and prisons. The cathedral had accumulated immense wealth in silver and other offerings, of all which it was rifled at the Revolution; an event more fatal to Avignon than to any other city, except Lyons. Avignon is surrounded by a wall built only for fiscal purposes, and the Rhone is crossed by a handsome bridge built by St. Benezet in the twelfth century from the produce of alms, and which yields 50,000 francs of annual toll. It would be profane for a traveller to leave Avignon without visiting the tomb of Laura in the church of the Franciscans, and making an excursion to the beautiful fountain of Vaucluse (*fig. 246.*), the scene of inspiration to Petrarch. Arles was, in early times, one of the most important cities in the south of France; under the Romans it was the seat of the prætorian prefect; in the ninth century it was the capital of a separate kingdom, and afterwards the seat of an archbishop, and of thirteen successive councils. It is still a large city, and presents the vestiges of a Roman amphitheatre (of which the interior area is now built upon), once capable of

containing 30,000 persons. Tarascon is still a flourishing place, above which rises the

246

FOUNTAIN OF VAUCLUSE.

ancient castle of the counts of Provence, now converted into a prison. On the opposite bank of the Rhone is Beaucaire, distinguished for its great annual fair, at which are still sold goods of various descriptions to the value of about 300,000*l*. Digne and Carpentras are of some importance as capitals of districts.

2408. *Marseilles and Toulon*, the two great southern havens, form now the most

important features of Provence. The commercial fame of Marseilles dates from early antiquity, when it was a Greek colony, and carried on almost all the commerce of Gaul. In modern times it has been the chief centre of the trade to the Levant; and though its prosperity suffered a total eclipse under the régime of Napoleon, it has since regained much of its former splendour. The harbour is spacious and secure, but is somewhat narrow at the entrance, and shallow. It is bordered by extensive quays of hewn stone, with spacious warehouses; and is filled with all the shipping peculiar to the Mediterranean, among which are galleys, and beautiful pleasure-boats with silk awnings; it is crowded with all the nations of that sea, Greeks, Turks, Jews, Spaniards, Italians, and loaded with the produce of Asia and Africa. It is compared by a late writer to Liverpool: the districts round the port are a nucleus of trade and dirt; but in the exterior, the streets are handsome, airy, and well built. Among other fine public buildings is the *hôtel de ville*, with its magnificent marble staircase. The *cours* is formed by two rows of fine trees bordered by handsome houses, and the central walk is crowded like a fair. The neighbouring plain is finely cultivated, but is bounded by bold and rugged mountains that rise above the range of vegetation. Toulon, though not a seat of commerce, is the chief naval station of France on the Mediterranean. It has two ports, the old and the new: the latter alone receives ships of war, and is bordered by most extensive arsenals, in which 5000 men are constantly employed. This port can contain 200 sail of the line; and without is a very spacious and well-sheltered roadstead. It is defended by two strong forts, which, however, were occupied in 1793 by the British, who, at the end of the year, were obliged to evacuate the place. This was the first occasion on which Bonaparte's military talents became conspicuous. Toulon is a clean, pleasant town, refreshed by streams of water, running through the streets. The adjacent country is wild and romantic, and interspersed with some cultivated valleys.

2409. *Dauphiné* is a region completely alpine, the two departments of the Higher and Lower Alps occupying the greater part of its surface. The mountains are chiefly calcareous, and broken into the most picturesque, peculiar, and romantic forms. Young even considers the scenery of Dauphiné, particularly along the Isère, as surpassing that of any other part of the Alps. In one of the most awful recesses of these rocks and wilds, at a distance from all the smiling scenes of earth, St. Bruno erected the monastery of the Chartreuse (*fig. 247.*), of which Gray has drawn so sublime and imposing a picture. There are

247

GRANDE CHARTREUSE.

other scenes emphatically termed the wonders of Dauphiné; as the burning fountain, the grottoes of Sassenage, &c. Although this part of the kingdom cannot be considered as productive, yet great numbers of cattle and sheep are reared on its high slopes by a simple race of men resembling the mountaineers of Switzerland; and even the silk-worm is bred in its lower valleys.

2410. *The cities do not require very particular notice.* Grenoble is a considerable place, not ill built, with a library of 60,000 volumes, and some other literary establishments. It took a conspicuous part in promoting the commencement of the Revolution, and was also the first town that opened its gates to Napoleon on his return from Elba. Gap is a pretty large but

poor old town, in a deep hollow, amid barren mountains. Vienne is a Roman city, and presents a temple, with several other interesting remains of that people. It has also a fine

modern cathedral with a very lofty spire. Valence has a military school, at which Bonaparte was educated. Near Tain is produced the celebrated wine called Hermitage.

2411. *The Lyonnais is a small territory*, penetrated by branches of the Alps, in some places rough and stony, in others finely diversified with hill and dale. Its chief interest, however, centres in the great city which is its capital.

2412. *Lyons (fig. 248.) is generally considered as the second city in France*, and as foremost

LYONS.

in regard to commerce and industry. It is on the whole a noble city. The quays along the Rhone are superb; the *hôtel de ville* is held to be second only to that of Amsterdam; the cathedral is highly ornamented in the florid Gothic style; and the squares, especially the *Place de Bellecour*, with its fountains and statues,

are nowhere surpassed. On the other hand, the old streets are narrow, bordered by lofty and gloomy walls, and divided by a muddy stream. To turn into them from the quays has been compared to entering subterraneous passages, watered by the sluices of Cocytus. Lyons suffered dreadfully under the sway of the jacobins, who made it a chief theatre of those atrocities that rendered them the horror of mankind. To say nothing of the massacres perpetrated under the appellations of *fusillades* and *noyades*, they studiously broke in pieces all the manufacturing machinery, while with barbarous hands they defaced all the ornaments of the city, filled up the fountains, broke the statues in pieces, and demolished the whole of the cathedral except the walls. Her citizens have made diligent efforts to restore her prosperity, and not without success; still, the want of capital and the stagnation of trade are serious obstructions, and cause the evils of poverty among a large population to be severely felt. The Lyonnese have the propensities usually observed in manufacturing places; they dislike the Bourbons, and the sight of an Englishman is wormwood to them.

2413. *Auvergne*, to the west of the Lyonnais, is the only mountainous and pastoral tract which France has peculiarly its own. It consists of a continuous range of mountains which have evidently been in a state of volcanic action, the country being covered with lava, and the houses built of it. From an elevated and extensive plain rises the great Puy de Dôme, nearly 5000 feet high, with about sixty attendant mountains, called in the country the giantess and her children. The country is diversified with many rugged and precipitous rocks, having castles and even towns built on them. Yet Auvergne is not a barren country. The Puys are mostly covered with herbage, and have large level plains. The natives are laborious, and rear large herds of cattle, which are almost wild; they are even said to beat off the wolf, the low of the animal attacked summoning all the rest to its assistance; but, in return, they cannot be milked unless the calf be on the other side. The people are homely, and very republican; they form themselves into a number of societies, of which the principle is a common table, attended however by the men only. In winter they take up their abode under the same roof with the cattle, which occupy each end, and by their heat save fuel, which is scarce. Clermont is a considerable town, perched on the top of a hill, and built of lava. It is extremely dirty, and Mr. Young compares several of its streets to channels cut in a dunghill; however, the mountain breezes purify the air. The cathedral, which was fine, was nearly destroyed during the Revolution. In the surrounding country are many curious caverns, petrifying wells, warm springs, cascades, &c. Aurillac also, Riom, and Thiers are elevated towns, commanding striking views of the rocks and cones of this remarkable chain.

CASTLE OF POLIGNAC.

Towards Puy en Velay, which naturally belongs to Auvergne, the rocks become still more steep and romantic, and among the castles seated in them, Mr. Young especially distinguishes that of Polignac (*fig. 249.*), the form and site of which appears to him so striking, as to cause all the feudal ages, by a sort of magic influence, to rise before the mind. St. Michael's church,

in the centre of the town of Puy itself, stands on the top of a very striking, almost precipitous rock, of tower-like form.

2414. *Burgundy and Champagne*, with the small adjoining provinces of Bourbonnois and

Nivernois, form a vast plain extending north of the provinces last described. Burgundy, however, is traversed by branches from the Vosges, forming hilly tracts of moderate elevation. This is the great country of wine, producing the finest in France, and, with very few exceptions, in the whole world. The surface of the vine-district is chiefly red sandstone rock, with very little soil. The vineyards are cultivated by small proprietors, who do not usually hold more than twenty or thirty arpents. It costs 21*l.* to plant an arpent in vines, and 1*l.* 5*s.* annually to keep it in repair. Three years elapse before it yields any wine, and six before it yields good wine. Common vineyards sell at 60*l.* an acre; and there are some that sell so high as 400*l.* The precariousness of the crop, however, and the want of capital, render this branch of industry a poor employment; and the

cultivators of Burgundy are the least flourishing of any in France. Few new vineyards are now laid down; though the capital invested in the old ones is a sufficient reason for keeping them up.

2415. *Of the chief towns*, the first in dignity is Rheims, a noble and ancient city, the ecclesiastical capital of France, where the kings were crowned and anointed. The cathedral (*fig. 250.*) has been considered the most splendid specimen of Gothic architecture existing, though some of its ornaments are not in the purest taste. The Hôtel de Ville is also fine; and the streets, unlike what is usual in old towns, are broad, straight, and well-built. Rheims is still the chief mart of that favourite wine called champagne, and from thence the connoisseurs of Paris take care to procure their supplies. Troyes, once celebrated for its great fairs, and noted as having given its name to the Troy weight, ranks as capital of Champagne, and is still a large and flourishing town on the Seine. Châlons sur Marne is also considerable, and, by a seemingly capricious choice, is the capital of the department of the Marne, instead of Rheims. Mezières and Sedan are strong frontier towns; the latter celebrated for its manufacture of fine woollen cloth, as well as for one of arms. Rocroy is

only distinguished for the signal victory of 1643, which first established the superiority of the French arms. In Burgundy, Dijon (*fig. 251.*), with its numerous and lofty spires,

CATHEDRAL AT RHEIMS.

DIJON.

presents a noble appearance to the approaching traveller; but it has lost much of its ancient importance. Its churches, now too numerous for the place in its reduced state, were dreadfully defaced and mutilated during the Revolution: one has been converted into a market

for fish, another into one for corn. The streets, however, are wide and clean. Dijon has a distinguished university, and can boast of giving birth to Bossuet, Buffon, and Crébillon. Autun attracts notice by a temple and other remains, which indicate its importance as a Roman city, also by a fine modern cathedral (*fig. 252.*). Auxerre still flourishes by the excellent wine produced in its neighbourhood, and is adorned with a cathedral and several lofty spires. Châlons sur Saône is a good country town.

AUTUN CATHEDRAL.

Sens, the see of an archbishop, and formerly the seat of several councils, presents still some noble monuments in decay. Moulins, capital of the rich plain of the Bourbonnois, though not handsome, is busy and cheerful, having a considerable traffic upon the Seine. Nevers, in Nivernois, is finely situated on the Loire, but is an ill-built and dirty town.

2416. *The provinces of Lorraine, Franche-comte, and Alsace* are less an integral part of France than a series of appendages obtained by conquest chiefly during the reign of Louis XIV. They remain still in many points connected with Germany. They are watered by the Meuse and the Moselle, tributaries of the Rhine; they are traversed by the chain of the Vosges, connected with the Swiss Alps and the Black Forest; their surface is rude and irregular; their wines have the same agreeable acid quality as the Rhenish. Even yet Alsace, both as to language and manners, is altogether German.

2417. *The cities are,* — Nancy, capital of the dukes of Lorraine, a race of gallant and accomplished princes. It is said to be the most elegant city in France, especially the new town, built in the sixteenth century. The gates appear almost like triumphal arches; the public buildings are numerous; the *place royale* and the adjoining area are superb. The place is lighted in the English manner. Metz is a larger town, and now more important, being one of the strongest of the French fortresses. It is nearly enclosed by the Moselle and the Seille, and entered by successive drawbridges. The usual complement of its garrison is 10,000 men. Metz is celebrated for its long and triumphant defence under the Duke of Guise against the army of Charles V. It is still a flourishing town, with numerous manufactures, and contains a library of 60,000 volumes. Luneville was for some time the residence of Stanislaus, the ex-king of Poland, who considerably embellished it; and it was the scene of Bonaparte's first triumphant treaty in 1801. It is now rather a poor place, having few manufactures. Another strong fortress is Verdun, a name but too familiar to English ears, as the scene of the iniquitous detention of our countrymen in 1803. It is well situated on the Meuse. Salins flourishes by means of the salt extracted from the brine-springs, which are found also in other parts of this territory. Besançon, in Franche-comté, was a city of the German empire till the treaty of Westphalia, when it was ceded to the Spaniards, from whom it was wrested by Louis XIV. It is a large and industrious place, particularly distinguished by a manufacture of clocks and watches, introduced towards the end of the last century, and employing about 1800 persons. It has also valuable scientific and literary establishments. Dôle is likewise a very ancient town, once the capital of Franche-comté. Vesoul and Lons le Saulnier are pretty good towns, and capitals of departments. In approaching Switzerland, the country becomes elevated, and the towns occupy picturesque sites. Ornans lies in a deep dell, skirted by green rocky hills, like Matlock. Pontarlier stands on a height having a strong castle which guards the passage into Switzerland. Nantua is placed in a nook between two enormous mountains. On crossing the Vosges appears the rich and fruitful plain of Alsace, more highly cultivated than any other part of the kingdom, except French Flanders. Here Colmar, Haguenau, Saverne, Weissemburg, are agreeably situated and rather thriving towns. But by far the most important place in this part of France is Strasburg (*fig. 253.*). It was early celebrated as an imperial

city, enjoying extensive privileges, and enriched by the navigation of the Rhine. Its prosperity was still farther promoted in consequence of the zeal with which, along with the rest of Alsace, it embraced the reformed doctrines. Strasburg and Alsace suffered a severe misfortune, by being, in 1689, subjected to France by Louis XIV. Yet the city retained privileges beyond any other in France, and continued to be distinguished both by wealth and intelligence. Its schools were considered second only to those of Paris, till the Revolution, when they were severely injured, and have not yet been fully restored. Strasburg, however, has still valuable institutions, both literary and economical, and is one of the greatest and most flourishing cities of France. Its ancient importance is attested by its cathedral or minster, one of the most splendid existing monuments of the Gothic. Its tower, 470 feet high, is said to be the most elevated structure in

the world, with the exception of the Great Pyramid of Egypt.

CHAP. VI.

SPAIN.

2418. *Spain forms the principal part of a very extensive peninsula*; the most southern, and also the most western, portion of Europe. It is only connected by an isthmus about a hundred miles broad, traversed by the Pyrenees, a chain holding the second rank among the mountains of Europe. Spain is thus almost insulated from the rest of the continent.

SECT. I. *General Outline and Aspect.*

2419. *The boundaries of the Peninsula* in general, are on the north, the Bay of Biscay; on the west, the Atlantic; but this coast for more than half its extent is occupied by Portugal, whose interior frontier forms to that extent the western boundary of Spain. The most southern point near Gibraltar is separated only by a narrow strait from the opposite shore of Africa. Eastward from this strait is the Mediterranean, along which the coast winds in a north-easterly direction, gradually receding from Africa, and facing at a great interval the western coast of Italy. From its termination, the Pyrenees stretch across to the Bay of Biscay, and form the lofty limit between Spain and France.

2420. *The extent of Spain*, north and south, is, from Tarifa Point in the straits, in 36° N. latitude, to Cape Ortegal in Galicia, $43^{\circ} 46'$; making $7^{\circ} 46'$ of latitude, or about 540 English miles. From east to west, the extreme points are Cape Creus, in Catalonia, $3^{\circ} 17'$ E. longitude, and Cape La Roca, $9^{\circ} 17'$ W. longitude; implying twelve and a half degrees, which, in this latitude, amounts to about 560 miles. Thus the Peninsula forms almost a square; allowance being made for the irregularity of its outline; and, the entire extent of Portugal being taken off, it is reckoned not to contain more than 176,600 square miles.

2421. *The surface of Spain* is strikingly irregular. It is traversed by long and lofty ranges of mountains, having plains of vast extent between them and the sea. These mountains may be considered as part of the great range which crosses Europe from the Black Sea to the Atlantic. The Pyrenees, common to France and Spain, form a long continuous line of lofty summits, the most central and elevated of which is Mont Perdu near the source of the Cincà, which the measurements of Ramond have fixed at upwards of 11,000 feet. Towards the sea, on both sides, the mountains sink into a more moderate elevation, and the barrier between the two kingdoms is less formidable. This great chain shoots lower branches into Catalonia and Navarre, presenting also some striking insulated peaks, among which that of Montserrat is the most conspicuous. From the western extremity of the Pyrenees, a great chain, which has been called the Iberian, reaches almost due south, forming the boundary of the fine plains of Aragon and Valencia. All the other ranges run from east to west. The Cantabrian is nearly a continuation of the Pyrenees: it stretches across the whole north of Spain, covering the provinces of Asturias and Galicia, and leaving only a narrow and rugged plain along the sea-coast. Parallel to this, on the opposite side of a vast plain through which the Duero flows, is another transverse range, bearing in its highest points the names of Guadarrama and Somosierra, and enclosing with its rugged and romantic cliffs the elevated palaces of San Ildefonso and the Escorial. On the opposite side of the Tagus and of the plain of Madrid is another parallel chain, the Sierra of Toledo. It borders the wide elevated plain of La Mancha; on the southern boundary of which is the more celebrated chain of Sierra Morena, the lofty barrier of the rich plains of Andalusia. Beyond these rises another longitudinal chain, of a peculiarly bold and lofty character, called the Sierra Nevada, from the snow which perpetually covers many of its summits; between which and the Mediterranean only a narrow though beautiful plain intervenes. These long and lofty ranges, as observed already, are separated by very extended plains, which, in the interior, are of great elevation, and even Madrid is 2000 feet above the sea: the plains along the Mediterranean, and almost on a level with it, display a profuse fertility, and abound in all the choicest fruits of a southern climate.

2422. *The rivers of Spain* form as important and celebrated a feature as its mountains. The Tagus and the Duero, rising in the Iberian chain, on the frontiers of Aragon, roll along the two grand central plains, receiving numerous though not very large tributaries from the mountains by which they are bordered. Unfortunately for Spain, they terminate in the somewhat hostile realm of Portugal, and are scarcely navigable above its frontier; so that the commercial benefits arising from them are of little importance. The Guadiana belongs to La Mancha, and on its approach to Portugal forms the boundary of the two kingdoms; but the high tract through which it flows is only distinguished for its rich pastures, and does not render its port of Ayamonte a place of any importance. Beyond the Sierra Morena, the Guadalquivir waters the plain of Andalusia, and has on its banks the noble cities of Cordova and Seville; while Cadiz, not far from its mouth, forms the chief emporium of Spain. Though its navigation is now much impeded, and practicable for large vessels only to Seville, it is the only river in Spain of much commercial im-

portance. The Ebro, which derives from its position a greater historical celebrity than any other, rising in the Cantabrian mountains, nearly crosses the breadth of north-eastern Spain, and separates Catalonia and Aragon from the extensive regions of the interior. Its banks at present afford few materials for trade, except a large quantity of timber. The Guadalaviar and Xucar in Valencia, and the Miño in Galicia, are also rivers of some magnitude.

2423. *The mountains of Spain* enclose no lakes, their waters finding a ready issue along the vast plains on which they border.

SECT. II. *Natural Geography.*

SUBJECT. 1. *Geology.*

2424. *The principal mountain chains in Spain* differ not only in their external aspect, but also in their internal composition: they appear more as different individuals than as members of a single system. They have this in common with one another, that their nucleus consists, in whole or in part, of primitive and transition rocks; but not only the species, but also the relations of these, vary in the different chains. A great body of granite, which seldom reaches the highest points of the country, and contains subordinate beds of gneiss and other primitive rocks, ranges through the Pyrenees properly so called. It is surrounded by a predominating mass of crystalline slate and of transition rocks, among which the most abundant are clay slate and limestone. On the contrary, on the western continuation, in the Biscayan mountains, the older rocks are not widely distributed, and appear first in Galicia, at the western extremity of the northern mountain chain, where, according to Humboldt, granite, accompanied by crystalline slates, appears again, and in great extent. The principal mass of the mountain chain which separates Old from New Castile is composed of gneiss and granite. In the chain of mountains extending between the Tagus and the Guadiana, according to Link, the principal rock is granite. The long

References to the Map of Spain and Portugal.

[illegible]

ridge of the Sierra Morena contains principally transition rocks; granite breaks out on its southern foot towards the Guadalquivir. This rock, so frequent in the Iberian peninsula, appears to be wanting in the highest southern chain. The middle mountain ridges consist of mica slate, abounding in garnets, which, in the ridges lying before them, passes into less crystalline mica slate, chlorite slate, and clay slate, which sometimes enclose beds, at times of vast magnitude, of compact limestone, marble, dolomite, and serpentine. On the south coast, newer transition slate and greywacke slate, with beds of flinty slate, lie here and there on the older slate. The basis or fundamental part of the rock of Gibraltar is of these rocks.

2425. *The structure of the chains of mountains* corresponds in general with their chief direction. Not only the alternation of the different rocks, but also the direction of the strata, are conformable with the direction of the chains: hence, in the greater part of Spain, the principal direction of the slaty rocks is from S. W. to N. E., or W. S. W. to E. N. E. But the inclination of the strata varies. In the Pyrenees, properly so called, the dip of the strata is conformable with the two acclivities of the range. In the Somosierra and Guadarrama ranges, the principal mass of gneiss dips S. E. towards the granite lying before it. In the Sierra Morena, the predominating dip of the slaty strata is towards the N. W., so that they appear to rest on the granite which breaks from under them. In the Sierra Nevada, the dip of the strata is conformable with the two acclivities of the chain. It is worthy of remark how the curvature of the south coast of Spain obeys the direction of the strata, and how the formation of the far-projecting southern point of the land also stands in connection with the direction of the strata. At the foot of the rock of Gibraltar, the slaty strata run nearly north and south with a rapid dip towards the east. The Gut of Gibraltar is therefore nearly at right angles to the direction of the strata. The rocky wall between the Mediterranean and Atlantic Seas, by this direction of the strata, must have opposed the strongest resistance to the currents. The primitive and transition rocks, in very different places, are rich in ores. The present mines are confined principally to the south-west and south-east parts of Spain. The mighty lead-glance veins of Linares occur in granite; the colossal deposit of lead-glance in the Sierra de Gador, which afforded, in the year 1828, 600,000 cwt. of lead, is distributed in masses (putzen), in a limestone which may be referred to the oldest transition rocks, and the rich mercury mines of Almaden are contained in clay slate. The secondary rocks also assist in forming the principal Spanish mountain chains, but in a different manner. They ascend to a great height on the Spanish side of the Pyrenees; even some of the highest summits are of secondary rocks. The western continuation of the Pyrenean chain consists, in the Biscayan provinces, principally of secondary rocks; and it is probable that the lofty limestone mountain ridges which separate Asturias from Leon are a continuation of the Biscayan secondary formation. On both sides of Somosierra the primitive rocks are skirted by those of the secondary class; but they are far from the middle and higher parts of the mountain chain. When we follow the road from Madrid to Andalusia, we meet with secondary rocks near the transition clay slate of the passes of the Sierra Morena; but we must descend very low on the south side before we meet with similar rocks. The high mountains of Jaen are formed of secondary rocks. In the northern *vorgebirge* of the Sierra Nevada, between Granada and Guadiz, there are secondary deposits, which are not, however, so considerable and extensive as to reach to the high ridges. Also in the vicinity of Malaga new secondary rocks lie on the foot of older mountain masses; and the ridges of secondary rocks extend from the hills of Ronda towards the southern extremity of Spain. The wonderful isolated rock of Gibraltar is also principally composed of new secondary rock. The distribution of the rock is not confined to the immediate vicinity of the higher mountain chains, but it extends from the one to the other, rises or falls in the intermediate spaces, and forms in this way the widely extended high table-land.

2426. *The most important of the Spanish secondary rocks* are the following; viz., variegated sandstone and marl, gryphite limestone, and the white limestone or Jura limestone. The first of these exhibits the same relations as in Britain, where it is known under the name of new red sandstone and red marl. The shell limestone, which, in Germany, is enclosed between Werner's variegated sandstone and the younger marl formations, is wanting in Spain, as is also the case in England. The sandstone and marl is rich in gypsum and masses of rock salt. At Vallecas, near Madrid, and in some other places, there rests upon it, in single beds, that rare deposit consisting of *meerschauum*, with nests of siliceous minerals. It is to this formation, which occurs widely spread over the high table-lands of Old and New Castile, that these countries owe the reddish-brown colour of their soil, and the tiresome uniformity of their surface. The lias formation is widely distributed in the northern provinces of Spain. It appears to reach a considerable height on the Spanish side of the Pyrenees. In the Biscayan provinces it exhibits the same characters as the gryphite limestone of the Weser, and is so widely distributed that nearly all the older rocks are covered by it. Here it is remarkably prolific in an excellent iron ore. The immense mass of sparry iron ore, converted by decomposition into brown and red iron ores of Sommorostro,

near Bilboa, and which probably forms the ironstone hills mentioned by Pliny in the 34th book of his *Natural History*, belongs to this formation. Probably also the vast beds of coal in the Asturias are subordinate to it. The white Jura limestone, which is one of the most widely distributed formations, is also of great geognostical importance in Spain. It forms, in most places, the immediate cover of the variegated sandstone and marl, and occurs in the north, and also in the south of Spain, in single ridges and great mountain masses. This formation is exhibited in its most characteristic forms in the narrow pass of Pancorbo in Old Castile, in the lacerated mountains of Jaen, and the isolated rocky wall of Gibraltar. Wherever it occurs, its presence is announced by the yellowish-brown colour of the soil with which it is covered.

2427. *Some members also of the chalk formation occur in Spain.* The sandstone of the rocky ridge of the southern coast, between Cadiz and Gibraltar, and the limestone in the district of Los Barrios, bring to our recollection the rocks of the Saxon Switzerland. The first agrees with the German quader-sandstein, the latter with the Saxon planer limestone, an equivalent for impure chalk.

2428. *Tertiary deposits occur in different parts of Spain.* In the south, particularly near the sea-coast, there is a deposit, filled with marine organic remains, in which calcareous sand and pebbles occur, partly in a loose mass, and partly more or less firmly compacted by means of calcareous cement. Judging from the included petrifications, among which are beds of oyster shells, this deposit, on which Cadiz stands, and which, in some places, rises into hillocks and low hills, belongs to the upper tertiary sea-water formation. Probably the tertiary deposit mentioned by Brongniart as occurring in the neighbourhood of Barcelona belongs to the same deposit. That freshwater limestone occurs in Spain has been sufficiently proved by the observations of Baron Férussac. The deposit very much resembles that so generally distributed in Germany, and is found in different parts of Spain, both in the interior and on the coast, and at different heights. The calcareous breccia, generally with a ferruginous basis, which occurs principally in the south-west, where it is widely distributed, belongs to the latest of the antediluvian deposits. It not only incrusts limestone rocks of different formations more or less thickly, but also fills up rents and fissures in them: thus it abounds among the calcareous rocks of Gibraltar, where it sometimes contains bones of quadrupeds no longer met with there. The formation of the breccia is ascribed to a catastrophe which affected different parts of the coast of the Mediterranean sea. As Professor Hausmann, to whom we owe the preceding details, had not an opportunity of travelling in Murcia, he was not able to confirm or reject the accounts of Spanish geologists, who maintain that it contains true volcanic rocks. The occurrence of other rocks, which are conjectured to have come from below, has been noticed in but few places. Characteristic basalt occurs in Catalonia. The porphyritic and basaltic-looking rocks extending from Cabo de Gata, and from Avila, on the north side of the Guadarrama range, are still problematical. Hypersthene rock has been found by Professor Garcia in the vicinity of Salinas de Poza, in Old Castile, in contact with Jura limestone. Professor Hausmann found, in the mountains of Jaen, near to variegated marl containing masses of gypsum, rocks of greenstone. Col. Silvertop describes tertiary deposits in Granada in the *Edin. New Phil. Journ.*

2429. *It may not be improper, from Professor Hausmann, to point out the influence of soil and climate on the other departments of nature, as also on the peculiarities and occupations of man.* A glance at the whole nature of Spain discovers a threefold principal difference. The northern zone, which extends to the Ebro, differs entirely in its characters from the middle zone; and this again is completely different from the southern zone, which is bounded on the north by the Sierra Morena, and a part of the Ostrandés. The northern zone, which includes Galicia, Asturias, the Biscayan provinces, Navarre, the northern part of Aragon, and Catalonia, is a widely extended mountainous and hilly country. The snow fields and glaciers of the Pyrenees on the one side; and on the other the north and north-west winds, have a marked influence in lowering the temperature of the atmosphere, and in increasing the supply of water. The increased humidity is favourable for vegetation, which, on the whole, very much resembles that of the south of France; and the variety of rocks containing lime, clay, and sand, and also their frequent alternations, operate beneficially on the soil. The soil every where invites to cultivation, and the Catalonians and Biscayans are active cultivators of the ground. The middle part of Spain, to which belongs Old and New Castile, a part of Aragon, Leon, and Estremadura, is not so favourably circumstanced. In general, we rarely meet with either beauty or variety of aspect. The extensive and lofty table-lands, destitute of trees, are dull and tiresome; their uniform and monotonous surface, formed by vast deposits of horizontally disposed secondary strata, is swept across by the wind, and burnt up by the sun's rays. Whichever way the eye turns, it meets with scarcely any thing but wretchedly cultivated cornfields and desert heaths of cistus. Seldom, in general, more in the southern than in the northern districts, plantations of olive trees afford a meagre shelter, and vary the scenery, although in an inconsiderable degree. Nothing, certainly, has so great an influence on these properties of nature, with which many of the peculiarities and

modes of life of man harmonise, than the high situation of the widely extended table-lands, and the uniformity of the rock which forms the support of the soil. It is owing principally to the horizontal stratification, and the want of water, that the great Spanish table-lands are so widely extended, and so little intersected by deep valleys. The rivers, in most cases, carry but little water in comparison with the magnitude of the land, and the number of considerable mountain chains; and it is further surprising how insignificant the waters of most of the Spanish mountain groups are, even when the qualities of the rocks favour the formation of springs. The causes of this great deficiency of water are principally the great dryness of the atmosphere, the inconsiderable cover of snow on the mountains, and its short continuance; the absence of forests, and the want of great moors on the heights, and the comparatively inconsiderable breadth of the mountain ranges. The southern and south-western part of Spain, which comprehends Andalusia, with Granada and Murcia, is very different from that just described. On the opposite side of the Sierra Morena the whole land has a more southern and foreign aspect, a breathing of that African nature, which announces itself not only by the world of plants, but also by the animal world, and man himself. The great difference of climate is produced by the southern situation, the exposure of the acclivity on the south and south-west to the African winds, and the strong reflection of the solar rays from the lofty, naked mountain walls. The mountain ranges are more closely aggregated, the valleys more deeply cut: there is no room for very extensive table-lands, and the more limited ones that occur, as those of Granada, are more amply supplied with water than those in the middle of Spain. Along with this arrangement, there is greater difference among the rocks, and also of their position. The south of Spain, therefore, possesses not only a much higher temperature, one fit for the orange and the palm, but also a more varied and a more favourable soil for cultivation. But these relations would have acted more beneficially if the air had been more humid, and moisture had been every where more abundant. The deficiency of moisture is the principal cause not only of the striking meagreness of phenogamous vegetation, on the most of the mountain acclivities, but also of the remarkable paucity of lichens and mosses on the mountains on the coast; and in connection with this is the fact, that the weathering of the rocks, and the reforming of the original surface of the mountains, assume there a somewhat different course from what is observed in places which are moister, and provided with a more powerful vegetation.

SUBSECT. 2. *Botany.*

"Oh! Christ! it is a goodly sight to see
What Heaven hath done for this delicious land!
What fruits of fragrance blush on every tree!
What goodly prospects o'er the hills expand!
(But man would mar them with an impious hand)."

2430. "*European Spain*," says M. de Humboldt, "situated in latitudes under which Palm trees (*Phoenix dactylifera* and *Chamærops humilis*) grow upon the plains, presents the majestic spectacle of a chain of mountains, the tops of which shoot up into the region of everlasting snow. By a levelling survey executed with the greatest care, it has been ascertained that in the Sierra Nevada of Granada, the Pico de Venleta rises 1781 fathoms (or about 11,353 English feet), and the Mulhasen 1824 fathoms (or 11,628 English feet), above the level of the ocean. None of the mountains of the Pyrenees are of so great a height; for Mont Perdu, the loftiest of the Spanish Pyrenees, is only 1763 fathoms, and the highest of the French Pyrenees only 1722 fathoms. The peak of Mulhasen, in the Sierra Nevada of Granada, wants only 76 fathoms of being as high as the Peak of Teneriffe. Yet even this summit, if situated in the same latitude as the town of Mexico, would not be perpetually covered with snow: for the never-melting snows begin under the equator at 2460 fathoms; under the twentieth degree of latitude at 2350 fathoms; under the forty-fifth, at 1300 fathoms; and under the sixty-second, at 900 fathoms."

2431. *Thus circumstanced in regard to climate*, and the elevation of its mountains, how greatly is it to be regretted that no country in Europe has been so little investigated in regard to its botanical productions! Enough, however, is known for our purpose, which may be collected from the different travels in, and accounts of, Spain and Portugal, and from the *Recherches sur la Distribution Géographique des Végétaux Phanérogames dans l'Ancien Monde*, already alluded to, by M. de Mirbel. This author considers the whole of this peninsula, with the exception of the northern part of Spain, which forms the shores of the Gulf of Gascony, and which belongs to the temperate zone, as entering into the transition zone. If, therefore, its vegetation has any affinity with that of France, it is only where its mountainous parts, especially the Pyrenees, resemble the mountains of France, and its warm districts are like the extreme south of France. In East Valencia and Murcia, in the south of Andalusia and the Algarves, in Western Alemtejo and South Estremadura, the rich and varied vegetation calls to mind the fertile plains of Syria. In Andalusia, frosts are unknown, and the snow, if it ever falls, melts the moment it touches the soil: so that it is not surprising that, in the cultivated parts, the Spaniards, long famous for their voyages,

should have introduced many vegetables from remote parts of the world ; thus giving a perfectly tropical appearance to the country.

2432. *The Erythrina Corallodendron*, or *Coral tree*, with its brilliant scarlet blossoms, the *Schinus Molle*, with its gracefully pinnated foliage, and the *Phytolacca dioica*, are introduced, with many other plants, from South America. Even the Bananas are common to the south of the Guadalquivir ; as are also the Cayenne Pepper ; and, in gardens, the *Convolvulus Batatas* or Sweet Potato. Every where about the rural habitations of the Spanish peasantry, the Date, the Orange (*fig. 255.*), the Lemon, the Olive, the Pomegranate, the Fig (*fig. 256.*), and the Mulberry, flourish nearly as well as in the native soil. Link notices the trees growing about Lisbon ; “ they are chiefly,” he says, “ Olive and Orange trees, Cypress, Judas trees : Elms and Poplars appear too. But of Oaks, Beeches, and Lime there are none, and very few Willows ; so that one may instantly perceive how different is the character of a Lisbon view from that of Germany.” The Orange is the most striking of these ; for there are many plant-

THE ORANGE.

which continually excites new admiration, though it is one of daily occurrence. One single tree frequently bears 1500 oranges, and examples are not wanting of their bearing 2000, and sometimes, though rarely, 2500. In the provinces they sell for half a farthing apiece. Figs are exported largely from the city of Faro ; they are the most important

THE FIG.

produce of the Algarve, and are brought down by the country people to the merchants in immense quantities. They are thrown in heaps in a building prepared for the purpose, where a syrup flows from them, which is used to advantage in making brandy. They are then spread to dry in the sun, in an open situation, where they are left for a few days in proportion to the heat of the weather ; after which they are packed into small baskets made of the leaves of the Fan Palm, and exported. “ Greece and the Algarves,” M. Link observes, “ are the only countries where caprification is practised ; for in the latter country are some varieties of Figs, and those very excellent, that fall to the ground immature, unless punctured by gnats.” Two ideas prevail respecting the effect of this operation ; the general opinion being, that the little insect, on entering the Fig, (which is known by botanists, to be a fleshy receptacle, including many, and often only barren flowers,) carries with it, from other figs that it has visited, and from which it comes loaded, the farina necessary for fertilisation : while others maintain, and among them M. Link, that the puncture caused by the insect gives a fresh stimulus and a new movement to the sap or juices of the fruit, thereby not only preventing the fall of the fruit, but rendering it sweeter and better flavoured ; and it is certain that many of our common fruits, when pierced by insects, acquire the sweetest flavour. The ancients perfected the figs in the Archipelago by means of an insect, a species of *Cynips* (*C. Ficus.*) In Algarve, besides the cultivated kind, another wild sort is grown ; in which the insects abound. These trees are recalled *Fijos de tora* ; and branches of them are, at the proper season, broken off, and suspended over those intended to be fertilised, when the little animals come forth, alight upon the fruits, puncture them, and aid their ripening.

2433. *Formidable fences* are made of the *Cactus Tuna* (*fig. 257.*), and the *Agave americana*, or *American aloe*. The former is often mixed with the Pomegranate, but of itself it

constitutes a hedge almost impervious to cattle. In Portuguese it is called, on account of

CACTUS TUNA.

its prickles, *Fijo do inferno*: the flowers are yellow and the fruit esculent; the latter is by no means unpalatable, and is regularly sold in Lisbon. Of the *Agave americana* we have already spoken, and shall, therefore, simply mention here, that its leaves undergo a process by which a valuable thread is extracted, known in Portugal by the name of *Filo da pita*. The largest and most perfect leaves are cut off, laid upon a board, and scraped with a square iron bar, which is held in both hands, until all the juices and pulp are pressed out; the nerves only remaining, when these are found easily separable into threads. Where pasturage is scarce, as in Algarve, the cattle eat the foliage of this plant, if cut into thin transverse slices.

2434. In *La Mancha* grows the *Esparto grele* (*Stipa tenacissima*), of which cords are made, and the foliage is sent in large quantities into Portugal for this purpose. To prevent the careless destruction of these valuable plants, penalties are inflicted on any person who ventures to gather them before the month of May, when they are in perfection.

2435. The *Carob tree* (fig. 258.) Link reckons the most beautiful of European trees. It attains a considerable

height, forming, with its large evergreen pinnated foliage, a head of considerable dimensions, and yielding a welcome shade. Among the foliage hang down the numerous long pods,

CAROB TREE.

which, when ripe, are used as fodder for cattle, especially the mules, and as meat for swine, though inferior to the acorns of the Evergreen Oak. Before the expulsion of the Moors, the Sugar Cane was cultivated to a considerable extent, and lately it has been re-introduced, at San Lucar, into a garden "d'acclimation," together with Coffee, Indigo, and Gum Arabic. A vast extent of country is covered by the *Chamærops humilis* (*Dwarf Palm* or *Palmetto*), growing in waste places. This vegetation, in part exotic, follows the coasts of the Spanish peninsula, to the east and to the west. It is diffused in all its luxury in the delicious territory of Valencia, where the agriculture of the Moors is still held in respect. With the species already named, are here cultivated the *Aloë perfoliata*, *Yucca aloifolia*, *Cassia tomentosa*, *Media Azedarach*, many kinds of *Mimosa*, *Annona*, &c. In the environs of Alicante the Date harvest is very abundant. This Palm there grows in large plantations, and often attains the height of 120 feet. It reaches along the entire coast, to the

40th degree, and perhaps higher. The *Agave* abounds in the environs of Tarragona, in the 41st degree; and the Olive continues to the shore of France.

2436. In general, the vegetation of the east of the Peninsula differs little from that of the other shores of the Mediterranean. The coasts of the Ocean, on the west, are less hot, according to M. Bory de St. Vincent, than corresponding latitudes on the east sides; so that the southern vegetation does not extend so far to the north. Be this as it may, the Date, the Lemon, the Orange, abound in Algarve and Alemtejo. The Orange grows plentifully in the environs of Oporto, in 41°; and the Olive extends to 42°. A great number of American plants, the seeds having been probably brought in ballast, are mingled, and as it were confounded, with indigenous species. Upon the whole, however, the vegetation may be considered as having more in common with that of the Atlantic than with the coasts of the Mediterranean. Link thus pictures the climate of Portugal, and its effects upon vegetation:—"A heat, equal to 96° of Fahrenheit, is not uncommon in this country; and, from comparative observations, it appears that the climate is warmer here than in Brazil, though the heat does not continue near so long. From Midsummer-day to the middle of September, rain is extremely uncommon, and even in the beginning of that month very scanty; the drought often continues much longer. Immediately after the first rains follow the autumnal flowers, the Meadow Saffron (*Colchica*, two species but little known); Saffron (*Crocus sativus*); the Autumnal Snowdrop (*Leucojum autumnale*); the sweet-smelling *Ranunculus bullatus*, and many others. These appear in the higher lands around Cintra, where the rains are earlier than in the low parts near Lisbon. Immediately after the autumnal flowers come the spring plants, owing to which the interval between spring and autumn is scarcely perceptible. In October the young grass springs up, and the new leaves shoot out, rendering it the pleasantest month of the year. In November and December fall heavy rains, with frequent storms. Days of perpetual silent rain are very rare, for in general it comes down in torrents. The brooks round Lisbon, which it was

a little while before easy to step over, and which wholly disappear in summer, now rush like torrents down the hills. This swelling of the streams renders travelling difficult at that season, and would retard the operations of war as much in winter as the drought in summer. In January, cold, clear weather often prevails, but becomes milder in February, which is generally a very pleasant month.

2437. *The most common vegetables of the plains of Spain* are the Cork tree (*fig. 259.*), the Ilex, and Kermes Oak (*fig. 260.*), the Bay tree, the Myrtle, the Phillyrea media and

CORK TREE.

KERMES OAK.

angustifolia, *Juniperus Sabina*, *Celtis australis*, *Pistacia Terebinthus* and *Lentiscus*; *Rhamnus Alaternus*, and many other species of this genus; *Viburnum Tinus*, *Osyris alba*, *Paliurus australis*, the Strawberry tree, the common and shrubby Jessamines, the Caper plant, and a great number of *Cisti* (*fig. 261.*) with other shrubs, whose foliage is of an

CISTUS.

CHESTNUT.

evergreen and coriaceous nature. Immense plains are clothed with *Lygeum Spartum*, and the running streams are bordered with *Bupleurum spinosum* and *Nerium Oleander*.

2438. *But it has been justly remarked*, that no country in Europe presents a more sorrowful aspect than the interior of the Peninsula. "No man, perhaps, saving a botanist," says Link, "could travel with any pleasure in the barren tracts of Old Castile; but this pursuit can render travelling both instructive and interesting, even in these, apparently, sterile wastes. Where forests have existed there, they have yielded to the stroke of the axe; and the naked soil remains without any culture. Vast chains of mountains spread out in all directions, and between them are extended the Parameras, more or less elevated plains, frequently as naked as the steppes of Siberia." M. Bory estimates at from 1800 to 2000

feet the elevation of the Paramera which divides the sources of the Douro and the Ebro. In the valleys formed by these rivers and their tributary streams, a vegetation of great beauty is found, partaking of that in the more temperate climates of the north. Here are seen small fields of Maize, and even of Rye and Barley, more rarely of Wheat, surrounded by lofty Oaks, Chestnuts, and Poplars, every tree supporting a Vine, which spreads over it and not unfrequently reaches to the very summit of the highest Oaks; while a cool refreshing shade usually abounds, adorning a cultivated populous country, every valley resembling a fairy land, enclosed between dark and rocky mountains.

2439. *The great mass of the forests* which have escaped destruction are mostly formed of Evergreen Oaks; among which, besides the other species already enumerated, are found the *Quercus Ballota*, *ægilopifolia*, *faginea*, *prasina*, *crenata*, *rotundifolia*, *humilis*, &c. The latter does not exceed six inches in height. In the valleys and on the mountains also, grow *Tilia europæa* (*platyphyllos*?) *Fagus sylvatica*, *Castanea vesca* (*fig. 262.*), *Taxus baccata*, *Pinus sylvestris*, *Fraxinus*, *Ornus*, &c. The commonest forest tree on the plains of the temperate zone, namely the Oak (*Quercus Robur*), inhabits the southern slope of the Pyrenees. It is said that this tree occurs also in some other parts of the Peninsula, and we are the more inclined to credit it, because the learned and accurate M. Desfontaines has ascertained its existence on the chain of the Atlas.

2440. *The vegetation which prevails* on the lofty mountains in the interior of Spain is almost wholly unknown to us. M. Ramond has made some interesting observations on that of the Pic du Midi, one of the highest of the Pyrenees; and has compared the plants of its most elevated summit, estimated at about 10,000 feet, with that of Melville Island, as described by Mr. R. Brown. The similarity is very striking.

Of these, eight of the Melville Island *lichens* and one of its *mosses* are found on the summit of the Pic du Midi; five others of the lichens, and one out of its two *hepaticæ*, and six of its mosses grow on the crags of the peak, or in its immediate vicinity.

SUBSECT. 3. Zoology.

2441. *The native zoology* has been so little investigated, that nothing beyond a meagre list could be furnished of indigenous animals. In the mountains of Asturias the Ibex is not uncommon, and the Alpine Squirrel (*Sciurus alpinus*) is only found in the Pyrenees. In the southern parts, bordering on the African shore, a few species of warblers have recently been found, which are as yet unknown to the rest of Europe. The European Bee-eater (fig. 263.) frequents the vicinity of Gibraltar in large flocks during the season of migration.

263

EUROPEAN BEE EATER.

2442. *Among the domesticated animals*, the horse and sheep of Spain deserve particular notice, as having been long celebrated throughout Europe. The best horses are generally about four feet six or eight inches high; they have all the fire, docility, grace, and action of the beautiful Arabians of Barbary (generally called Barbs), and there can be no doubt of these noble animals having been introduced by the Moors, and crossed with the native breed: those of Andalusia, Granada, and Estremadura are the most distinguished. At Xeres are

found two perfectly distinct races; the one, which possesses the fine qualities above mentioned, is still preserved in all its purity at the Chartreux. The other race is larger, stronger, less elegant, and used for common purposes. Latterly but little care has been bestowed in keeping up the more noble breed, so that fine horses are not so common in Spain as formerly.

2443. *The mule*, in so mountainous a country, is particularly useful, and, with the ass, is principally used for conveying goods in the interior; the breeds of the latter are very fine, and are hardly excelled by those of Egypt. Spain is still famous for its merino race of sheep (fig. 264.). The flocks are kept constantly travelling during the greater part of the summer, but are carefully pent up in winter. This race, subdivided into breeds, is

264

MERINO SHEEP.

extended over the greater part of Spain; but those of *Cavage*, and *Negrata* are the best. A third breed, the *Souan*, appears more hardy, and passes the winter in Estremadura, Andalusia, and New Castile: these three constitute the *Transhumante*, or travelling race, to distinguish them from the *Estantes*, or those of a somewhat inferior breed, who do not migrate. The best fleeces are those which appear almost black on their surface, caused by the dust adhering to the peculiar greasy pile; for it is invariably found that such fleeces are of the purest white beneath. The merinos, dispersed by George III. over

England, have incalculably improved our own races. By great care and expense on the part of the native graziers, this valuable race has likewise been introduced in the distant regions of Australia with equal success. There is a very large breed of oxen in the country round Salamanca; but the cattle of Spain have been much neglected; the mountaineers deriving all their milk and butter from goats. The spaniel appears to be a breed of dogs originating from this country; and the Spanish pointer is considered to have a greater acuteness of scent than that of Britain.

SECT. III. Historical Geography.

2444. *The earliest inhabitants of Spain*, like those of Gaul and Britain, were of the Celtic race, and from the river Ebro (Iberus) were called Celtiberi. The whole country was by the Greeks called Iberia, and sometimes, from its western position, Hesperia. The people, like those of the rest of Europe, were divided into a number of small tribes, hardy and warlike, who often showed a peculiar attachment to national independence, and obstinacy in its defence.

2445. *The Carthaginians* were the first civilised people who occupied Spain, which, for several centuries, was considered as theirs. They founded colonies on the most advantageous points, worked its rich silver mines, and easily allured many of its brave but poor inhabitants into their mercenary armies; they were far, however, from having thoroughly subdued the Peninsula, the people of which, on the rise of the Roman power, endeavoured by its alliance to emancipate themselves from the Punic yoke. The siege and fall of Saguntum seemed to have extinguished these hopes, and to have secured the ascendancy of Carthage; but the events which marked the close of the second Punic war completely humbled that proud republic, and put an end to its dominion over Spain.

2446. *The Romans*, by the capture of Numantia in B. C. 134, established their supremacy

over Spain, undisputed by any other nation ; but the complete subjugation of its inhabitants was a long and arduous task, to which the utmost exertions of Cæsar and his lieutenants were not fully adequate. Spain, however, was at length reduced to a province, divided by Augustus into three parts : —Tarraconensis, the north and east ; Bætica, the south ; and Lusitania, Portugal. The Spaniards even became civilised and peaceable subjects ; so that when Rome, sinking under its own weight, was unable to defend them, they could not resume their early independence, but fell a prey to the Vandals, Goths, and other barbarous hordes that poured in from the north of Europe.

2447. *The Goths*, in this terrible struggle, finally prevailed ; and in 418 a Gothic dynasty was fully established over Spain. These barbarous invaders appear here, as elsewhere, to have expelled or extirpated the native people, whose features and language are recognised only in some of the higher mountain districts. After a sway of three centuries, the Goths were destined to yield to a new people, coming from a remote quarter.

2448. *The Arabs*, rendered invincible by fanaticism, had over-run all the north of Africa, and established a powerful kingdom in Fez. The vengeance of Count Julian invited them over, and opened the way for them ; their immense host covered the plains of Andalusia ; Roderick, the Gothic king, was totally defeated. The invaders then over-ran the whole kingdom, with the exception of some mountain recesses, in which a remnant of the Gothic chiefs found shelter ; they even passed the Pyrenees, and seemed about to over-run all western Europe. But Charles Martel met them on the plains of Aquitaine ; and, after a dreadful battle of three days, they were signally overthrown, and never again attempted to pass the Spanish frontier. Meantime Don Pelayo, and other chiefs of the Gothic race, again raised the national standard in the mountains of the Asturias : then commenced a contest of 700 years, distinguished by numerous heroic achievements and memorable events, which gave to the Spanish character that romantic and adventurous cast which it has never wholly lost. The Arabs or Moors still retained the finest provinces, and the courts of Cordova and Granada were the most splendid and polished in Europe. The Spaniards, however, under a succession of able chiefs, and particularly of their great hero the Cid, gained ground : new kingdoms were successively founded ; which all merging into those of Castile and Aragon, comprehended the whole of Spain, except the extreme southern kingdom of Granada.

2449. *Spain was again formed into one great kingdom* by the union of the crowns of Castile and Aragon, under Ferdinand and Isabella, in 1474, and by the final overthrow and expulsion of the Moors. From this period commences the most brilliant era of her annals. The discovery of America, the conquest of the golden regions of Mexico and Peru, and of other dominions so extensive as to make it a plausible boast that the sun never set on them, threw an almost unrivalled lustre around the Spanish crown. Under Charles V. and Philip II., Spain continued the most powerful kingdom, and her armies the most formidable, of any in Europe. The throne derived even an addition of apparent lustre from the subversion of the popular part of the government, and the conversion of a body of grandees, once the proudest in Europe, to the condition of humble vassals.

2450. *The decline of Spain*, though its causes had begun to operate, did not become perceptible till after the death of Philip II. A gloomy indolence and degrading superstition now marked her councils ; her armies were vanquished by the French under Condé and Turenne ; she lost her place and rank in Europe. The trade with her vast colonies, fettered by absurd restrictions, became profitable only to the industrious nations which supplied its materials. The war of the succession drew notice towards this country, and called forth some displays of national energy ; but the Bourbon dynasty, which it placed on the throne, soon relapsed into the characteristic indolence, and Spain became little more than a dependency of France. We know not whether to designate as an era, the train of remarkable events which have occurred between 1808 and 1822. The Spaniards excited the admiration and astonishment of Europe by their daring defiance of the power beneath which the greatest sovereigns had been reduced to the rank of vassals. Their subsequent exploits did not altogether correspond to this beginning. Still, their resistance, considered as that of a people, was, on the whole, obstinate and glorious ; it even appeared that there had been formed a body attached to popular government, and eager to redress the political grievances under which Spain laboured. Ultimately, however, the eagerness with which the majority of the nation acquiesced in the system of absolute power, re-established by foreign interference, tarnished its honour, and reduced it again to that imbecile and degraded state in which it had existed for several centuries.

SECT. IV. *Political Geography.*

2451. *The constitution of Spain* ever since the downfall, of her liberties under Charles V. has been the most despotic of any in Europe, except Russia and Turkey. The Cortes, that powerful assembly, whose privileges were greater than those of any other European representative body, have since that period been rarely assembled, and then only partially, on occasions of mere form. The only two bodies which possess any influence, are the council

of state and the council of Castile; but as these are entirely under the appointment and direction of the monarch, they form little more of a check upon absolute power, than the Turkish divan.

2452. *Two attempts to restore a representative form of government* have lately been made, under circumstances which must be familiar to our readers. Unluckily, the leading or liberal party were hurried, on this occasion, into an opposite extreme; adopting the system of universal suffrage, forming themselves into one house, and allowing only a temporary veto to the monarch. This system, which excluded the nobles and clergy, the most wealthy and influential bodies, was from the first decidedly unpopular; and Ferdinand found it easy, first without, and afterwards with, foreign aid, to subvert it, and to re-establish in full plenitude the despotic sway exercised by his predecessors.

2453. *The grandees and other privileged orders* in Spain are distinguished for their pride beyond any others in Europe. Even Charles V. was baffled in his attempt to retrench the right of wearing the hat in the royal presence. The Spanish nobles impair their fortunes less by extravagance than those of the same rank elsewhere; and as they intermarry only with each other, the number of titles, or *hats*, as they are called, continually accumulates upon single heads. The dukes of Medina-Celi, of Alba, of Infantado, of San Estevan, of Ossuna, and some others, hold possessions truly immense, covering whole provinces. They are administered, indeed, in the worst possible manner, being kept in their own hands, managed by tribes of factors or intendants, of whom some nobles keep 300; so that it is truly astonishing that they should sometimes yield 50,000*l.* or 80,000*l.* a year. As these grandees, however, live not on their estates, but in the cities, in secluded pomp, they have lost all their feudal influence, and the ties which united them with the greater body of the people. The *hidalgos*, claiming nobility by descent from the members of great families, are much more numerous, and form, in some provinces, a large proportion of the inhabitants. They are often reduced to great poverty; in which they display that union of pride and indolence which has been supposed characteristic of the Spaniard. Mr. White mentions a species of illustrious birth quite peculiar to this country, consisting in a pure Christian descent, without any mixture of Jewish or Moorish blood, which last is supposed to produce so deep a stain, that no time can efface it. The clergy, moreover, exercise a paramount influence over the minds particularly of the lower orders, and have been the main spring in all the movements, good or bad, which for a long time past have taken place in the Peninsula.

2454. *The revenue* of Spain, though levied with little regard to the comfort and well-being of the subject, has never risen to any great amount. Yet she is the only power which ever derived any from her colonies; as the *quinta*, or royal fifth, of the mines of Mexico and Peru, after every deduction, brought home considerable treasure: but this source of wealth is now withdrawn. The other taxes were the most ruinous to industry and trade ever contrived by any government. The alcavala, or impost upon each transference of commodities from one hand to another, seems expressly destined to impose fetters upon commerce; while the royal monopolies of salt, lead, powder, tobacco, and other articles in general use, have the usual pernicious effects. Combined with those prohibitory clauses, by which Spain endeavoured without success to prevent her industrious neighbours from supplying the wants of her American colonies, they gave rise to a vast contraband, carried on in almost open defiance of government. Hence the taxation of Spain, though highly oppressive to the nation, yields very little to the crown; being in a great measure absorbed by the support of the individuals employed in its collection, who are said to amount to 16,650. Although, therefore, the entire sum taken from the people has been suspected not to fall short of 12,000,000*l.* sterling, the receipt by government in 1828 did not exceed 5,980,000*l.* The expenditure in that year was for the army, 2,650,000*l.*; navy, 400,000*l.*; marine, 1,445,000*l.*; justice, 145,000*l.*; state, 108,000*l.*; royal household, 505,000*l.* At the same time, Spain is burdened with a debt of 160,000,000*l.* sterling, of which the revenue would be wholly inadequate to defray the interest, had not more than half consisted of the *royal vales*, which do not bear any. Under the constitutional government a considerable addition of debt was incurred, which, however, Ferdinand has cleared off by refusing to acknowledge it; while he himself has vainly attempted to raise a loan to any amount.

2455. *The navy*, at the commencement of the late war, was at least respectable, and a formidable auxiliary to France. The fatal days of St. Vincent and Trafalgar, and the fruitless expeditions to South America, have reduced it to absolutely nothing. In 1823, there was only a single ship of the line, the *Asia*, which, being sent out to South America, surrendered to the Peruvian government.

2456. *The army of Spain*, which, under Charles V. and Philip, was the bravest and most formidable in Europe, has for a century and a half enabled her to rank very low among military nations. It is, however, at present the best organised part of her establishment. According to the author of "A Year in Spain," it consists of 25,000 royal guards, and 55,000 troops of the line and provincial militia, which, being commanded by experienced officers, formed during a period of protracted warfare, possess a considerable degree of efficiency; and their discontent being an object of dread, every effort is made to pay them regularly. The royalist volunteers, amounting to about 300,000 men, form a band of armed fanatics almost

entirely under the command of the priests and monks, and seeking in their favour to lord it both over king and people.

SECT. V. *Productive Industry.*

2457. *In respect to industry and wealth*, Spain, which had every opportunity within and without of becoming the foremost nation of Europe, is, in fact, the poorest and the most uncultivated. The insecurity of property, and the multiplied restraints imposed by an unenlightened government, appear to be the main causes which have paralysed all branches of industry. The furious bigotry of its monarchs, in particular, led to the most suicidal acts against the public weal. At the commencement of the fifteenth century, the country contained a numerous population of Jews and Moors, who formed its most industrious and wealthy inhabitants, and rendered it the most flourishing kingdom in Europe. The Jews, unless in the alternative of feigned conversion, were expelled from the kingdom by Ferdinand and Isabella, the Moors by Philip III. Although it appears to be upon exaggerated estimates that Spain has ever been supposed to have previously contained 20,000,000 of people, yet it cannot be doubted that the emigration of mercantile communities, with their capital and machinery, must have struck deeply at the root of the national prosperity.

2458. *Spanish agriculture*, it must be confessed, has some obstacles to struggle against. The territory, as we have had occasion to observe, is traversed in every direction by chains of rugged, and often barren, mountains. Yet these elevated provinces being the seats of comparative liberty and industry, are, on the whole, the best cultivated and the most populous. The great extent and continuity of these chains certainly present serious difficulties to the transport of grain. When government were bringing a supply from Old Castile to the capital, it was found that 30,000 beasts of burden were necessary to convey 2000 quarters. Another great impediment to effective agriculture consists in the habit, partly oriental, partly formed during a long internal warfare, which leads the farmers to crowd into towns, and thus live often at many miles' distance from the fields which they cultivate. In many cases they merely pitch their tents during seed-time and harvest, and at other seasons pay only occasional visits. They are also very poor, destitute of capital, and oppressed by the burden of tithes and other exactions.

2459. *The grain* produced in Spain is of admirable quality; the wheat of Andalusia bearing a price ten or fifteen per cent. higher than that of any foreign wheat brought to the markets of Cadiz. But a deplorable defect appears, when it is stated that Spain, a country purely agricultural, does not grow corn for her own use, but makes a regular importation. This, however, according to Bourgoing, amounts only to 2,000,000 fanegas or 400,000 quarters; a small proportion of the entire consumption, which may be estimated at 12,000,000 of quarters. The agriculture of Spain, however, produces three valuable articles; wool, wine, and barilla.

2460. *The wool of the merino* is of almost unrivalled fineness, though dearly purchased by the system upon which it is produced. Vast flocks, amounting to 20,000, 30,000, or even 60,000, belong to the grandees, convents, and dignitaries of Spain. After being pastured, during summer, on the sides of the mountains of Leon and Old Castile, they descend, in winter, chiefly to the plains of Estremadura. According to the rules of the powerful society of the *mesta*, composed of the above high members, they must pass freely, and be allowed, on payment of a very inadequate rent, to pasture upon all the unenclosed lands, which form the bulk of those in Spain. The entire number of sheep in all these wandering flocks is reckoned at 5,000,000; and there are a great number which remain stationary, and enjoy privileges nearly similar. The annual shearing takes place on a great scale, and with much celebration; and the wool is carefully sorted into three kinds, according to the part of the body from which it is taken.

2461. *The wines* of Spain are produced on the fine plains of the southern provinces. The most important is the Xeres, or sherry, which has come into such general use with the English nation. Mr. Jacob reckons that 40,000 pipes are produced in the plain of Xeres; of which 15,000 are exported, almost the whole to England. Around Malaga is made wine still more valued, though not in such quantity; which when white is called *mountain*, when red, *tent* (tinto). The northern and central provinces yield wine only of inferior value.

2462. *Barilla*, the finest known species of ashes, and highly useful in glass-making, bleaching, and other processes, is procured by burning various species of saline and aromatic plants in the provinces of Murcia and Valencia, and is one of the few articles which other nations can nowhere else procure of equally good quality. Silk and oil, in the Mediterranean provinces, are only limited by the want of culture or demand.

2463. *The manufactures of Spain* have been of little importance since the expulsion of the Moors. That industrious people introduced the silk manufacture; a branch entirely suited to a country where the material is produced in the greatest perfection; but it is now generally decayed, unless in Valencia, where it was supposed lately to employ 3000 people. The blades of Toledo were once famous over Europe, and the city has still a royal manufactory of swords, though of little importance. The Spanish government has devoted rather an extraordinary attention to manufactures, but unfortunately seeks to promote them by the king becoming himself the

producer. He has established a great fabric of broad cloth at Guadalaxara, which, having fine materials at hand, is rather thriving. Yet Spain does not supply herself with fine cloth. Other royal works are those of porcelain, at San Ildefonso; paper, in Segovia; cards and tapestry, at Madrid: all rather for show than use.

2464. *Commerce*, for which Spain seemed to have monopolised the most extensive materials, has long been in a state, at least, as low and depressed as any other branch. It has suffered severely, indeed, from the immense importance attached to it by the government, which actually crushed it to pieces in the attempt to prevent any portion from escaping. To absorb within their own circle the entire treasures of Mexico and Peru, was the first policy of the Spanish sovereigns. The gold and silver of those regions were to be brought exclusively to Spain, never to be taken out of it, and only the produce and manufactures of that country to be sent in exchange. By a sad fatality, the commerce of the colonies was carried on almost entirely by French and English merchants; nearly all the goods exported thither were foreign; and Spain, of all her neighbours, was the most destitute of the wealth accruing from this trade. These colonies, with the exception of Cuba and the Philippines, are now gone, and with them the greatness of Cadiz, which, by the absurd monopoly granted to her, became one of the principal emporia of Europe. The trade of Spain consists now in the export of wines, fruits, brandies, wool, silk raw and manufactured, lead, quicksilver, barilla, and a few other articles, which, according to a very imperfect document, issued by the Spanish government, amounted at 1826 to about 1,584,000*l*. Of this, 241,000*l*. was stated to be to the colonies. Her imports consist of sugar, cocoa, salt fish, spices, wood, rice, butter and cheese, hides, cotton wool, and almost every species of manufactured commodity. They are stated for the same year at about 3,267,000*l*., of which 724,000*l*. was from the colonies.

2465. *Internal communication* is a particular in which Spain actually labours under natural disadvantages, from the obstructed navigation of its rivers, and its long and steep chains of mountains. These obstacles the government has endeavoured to surmount by vast but ill-executed projects of improvement. They had conceived the plan of a grand canal, which, passing through Asturias, Old Castile, and Aragon, might join the Mediterranean with the Bay of Biscay. Of this mighty undertaking only two small portions exist; the canal of Aragon, running parallel to the Ebro from Saragossa, and that of Old Castile along the Pisuerga and Carrion by Placencia; but as neither of them makes any approach to the sea, their benefit is very limited. The main roads maintained by government between Madrid and the other great cities are good, and the mails well conducted; but most of the other communications are mere tracks worn by the feet of mules, which are chiefly employed in the conveyance of goods.

SECT. VI. *Civil and Social State.*

2466. *The population of Spain*, according to a census made in 1798, amounted to 10,351,000. It was generally understood, however, that the jealousy of the people, and all the obstacles usually encountered in such undertakings, operated to a peculiar extent in diminishing the amount. The census, in 1787-8, gave only 10,268,000, of which 188,600 were churchmen; and among these, 61,000 were monks, and 32,500 nuns. There were 480,000 hidalgos; 34,000 merchants; 40,000 manufacturers; 271,000 artisans; 907,000 peasants, 960,000 day-labourers; 280,000 domestic male servants. A census was undertaken in 1826, which was not fully completed, but carried so far as to prove that the number of inhabitants must be considerably greater than the above: it is estimated by Minano at 13,732,000; by Hassel at 13,953,000.

2467. *The national character* of the Spaniard is marked by striking features. The genuine Spaniard is grave, proud, adventurous, romantic, honourable, and generous. It has been insinuated that this is the Spaniard of the fifteenth century, of whom the Spaniard of the present day is only as it were the shadow. But though the higher ranks have certainly lost the original stamp, and become frivolous and dissipated, the body of the people, and especially the peasantry, form a very fine race. Even among the former, the late troubles brought forward signal displays of heroism, though, as too often happens in such cases, equally base examples of treachery. In the virtue and wisdom of the best Spaniards, there is apt to be something speculative and theoretical, not applicable to the practical purposes of life; a want of the wisdom of action. In prosperous circumstances they readily give way to supineness and false confidence; but in sudden and overwhelming vicissitudes, which sink the spirit of others, their latent energies are roused, and they display unexpected and surprising resources. Although assassination, which was once the reproach of Spain, is greatly diminished, yet a promptitude to fight and to shed blood, characteristic of all nations imperfectly civilised, is still prevalent. It is accompanied with a readiness to rise in tumultuary insurrections, and an unwillingness to submit to the restraints of discipline. The jealousy which was wont to dwell so deep and dark in the mind of the Spanish husband, has been superseded by a general laxity of morals. The custom is said to pre-

vail, that every married lady should have a *cortejo* or gallant, corresponding to the Italian *cicisbeo*; and though the usage may not be so decidedly criminal as it appears to strangers, it is certainly inconsistent with those habits and feelings which form the felicity of the matrimonial state. In this singular relation fixed rules are observed, and a certain fidelity is exacted; the jealousy of the husband is assumed by the *cortejo*; and the lady who changes, at least with any frequency, this object of attachment, loses *caste* in the eyes of the public.

2468. *The religious state of Spain* need only be mentioned to suggest the dark and gloomy features by which it is marked. That bigotry and superstition which the Romish faith contracted during ages of darkness, and which in all other countries is so much abated, retains nearly its full force in Spain. The Inquisition, that frightful tribunal, the disgrace of modern Europe, which here held its central seat, kept alive its fires against all who exercised their reason on a subject connected with the national faith. The order of Jesuits, who have been called the militia of the Romish church, originated also in this country. The Inquisition perished in the late struggle; yet a numerous body still call aloud for its re-establishment; and the most liberal rulers, whom the revolution raised to power, durst not attempt any approach to toleration, or to trench upon the "catholic religion one and indivisible." This spirit of bigotry and superstition is deeply diffused through the nation, who, if they no longer demand that heretics shall be committed to the flames, never doubt at least of the future tortures to which they are destined. All the childish and absurd customs which marked its prevalence during the dark ages, are preserved nearly unaltered; the processions and exhibitions, in which the events of sacred history are represented, often in a familiar and ludicrous manner; the endless festivals, which impoverish the nation, and favour its natural indolence; and the zeal of multitudes, who are induced by mistaken piety to withdraw themselves from their families and the world. Mr. Blanco White has given a striking account of the artifices by which the young female is led to make the irrevocable sacrifice; the respect and importance attached to her during the period of noviciate; the ceremonies, which resemble those of marriage, even the name of bride being given to her; and the disgrace attached to a retraction. Yet it appears evident, from the same author, that this profession is often deeply sincere; that it aids in producing that strong moral feeling which prevails throughout the nation; that many are even tormented by minute conscientious scruples; and that, with such persons, absolution, founded on false pretensions to penitence, is considered as aggravating the guilt. At the same time, there is a combination of deep devotion and dissolute conduct, which not only rapidly succeed, but actually coexist, in a manner never seen in any protestant society. It may be observed, that amid this thick darkness which covers the nation, a body of men has lately arisen, of active and enquiring minds, who have discerned the errors of the national creed, and have passed to the opposite extreme. They are comparatively small in number, however; and, as already observed, even in their greatest triumph, although they considerably reduced the conventual establishments of Spain, they never durst attempt to introduce the toleration of any form of worship different from the catholic.

2469. *Spanish literature*, during the era of the national glory, supported itself at least on a level with that of any other nation in Europe. Spain had, as it were, a literature to itself, scarcely any of the productions of which, if we except the inimitable satire of Cervantes, became familiar to the rest of Europe. During the middle age, she was rich in chivalric romance, the taste for which, however, was banished by the appearance of Don Quixote, a change which some lament, as having led to the decline of the national spirit. The poetry of Spain, roused by so many vicissitudes of internal revolution and transmarine triumph, took a somewhat lofty flight. The *Araucana* of Ercilla, celebrating her conquests in the New World, is named together, though not on a level, with the best modern epics. Garcilasso de la Vega, Villegas, Mendoza, and others, chiefly officers in the army of Charles V., introduced a style formed on the Italian model; and, having the advantage of a noble and sonorous language, worked up their verses to the highest polish. But it is in the drama that the Spaniards have been chiefly distinguished. Lope de Vega and Calderon, indeed, construct their plots with an entire disregard of the unities, filled with extravagant incidents, and strained and artificial sentiments. But they display an inexhaustible fertility of invention, and often strong traits of character; so that, though they never could be transferred entire to any other stage, they furnished useful hints both to the French and English dramatists. Mariana's History of Spain ranks among classical productions; while Herrera and Solis, though of inferior merit, have produced valuable histories of the Spanish transactions in the New World. To Don Antonio de Solis the Spaniards are willing to ascribe that inimitable satire on human character and manners, *Gil Blas*, which must, they say, have been written by a Spaniard and a courtier. As such, he might rejoice that it had amply fulfilled his intentions without compromising his security, and could very well afford to dispense with the fame which redounded to its reputed author, Le Sage. These writers belong to the classic age of Spain, which nearly expired with the seventeenth century; but of late the intellectual spirit which has spread so actively throughout Europe, has penetrated into Spain, and made vigorous struggles against the night of ignorance and prejudice in which that country was involved. Campo-

manes, Ustariz, Jovellanos, and Arguelles, have endeavoured to trace the causes which have paralysed Spanish industry, and to discover the means of reviving it; Feyjoò has done much to rouse a spirit of reflection; Yriarte, Isla, and Melendez Valdez have produced agreeable miscellaneous writings; and Moratin has adopted a more regular drama, formed on the French model. There are extensive public libraries; one, the royal library in Madrid, consisting of 130,000 volumes, with valuable manuscripts, and a rich collection of medals; and others in the great provincial towns; but the prevalence of monkish legends, and the prohibition of many of the most important standard works, greatly limit their value. The universities are numerous, and that of Salamanca once perhaps the most celebrated in Europe; but education being conducted upon obsolete and scholastic principles, and impregnated with the national bigotry, they have long ceased to attract students from any place out of Spain. Some of the younger members were supposed to have embraced novel ideas in regard to religion and government; whence they have become objects of jealousy to the government, which will probably be little anxious to rescue them from that decay into which they were thrown by the events of the revolution.

2470. *The fine arts*, especially painting, could boast in Spain of a distinguished school, marked by features strikingly national and original. It is characterised by depth, force,

THE GUITAR.

great truth of nature, and a warm expression of devotional feeling. Murillo, Ribeira (self-named Spagnoletto), and Velasquez, are those alone whose works are diffused throughout Europe; but by those who have visited Spain, Cano, Juanes, Ribalta, and Morales are mentioned in terms of equal praise. The Escorial and other royal palaces are likewise adorned by some of the finest pieces of Raphael, Titian, and Rubens. This taste seems to have declined with that of literature; and Townshend observed that the nobles set little value on the magnificent collections with which their palaces were adorned. Of late the efforts to revive painting have been considerable, but without producing any artists of much celebrity. The Spaniards are fond of music, but delight rather in detached airs for the serenade and ball, than in that higher class in which the Italians and Germans excel. The guitar (*fig. 265.*) as an accompaniment for song, and the castanets for the national dance, are characteristic Spanish instruments.

2471. *The Spaniards have favourite and peculiar diversions.* They are most passionately attached to the bull-fight: a large space is enclosed, sometimes the great square of the city, around which the people sit as in an amphitheatre. The bull, being introduced, is first attacked by the *picadores*, or horsemen armed with spears; a desperate conflict ensues; the horse is frequently killed, or overturned with his rider, when persons on foot run in, and distract the animal, by holding up different kinds of coloured stuffs. He is next attacked by *banderilleros*, or footmen armed with arrows; and not only their skill, but their dexterity in escape, are the subjects of admiration: at last, when the animal is completely covered with wounds, the *matador* or slayer appears, and closes the scene. Tumultuous applause or hissing from the populace accompanies every part of this savage performance, according to the respective merits of the bull or his assailants. The comparative excellence of different

THE FANDANGO.

matadores becomes often a party question, and the subject of keenly agitated discussion in the circles of Madrid. Wounds frequently, and death sometimes, are the result to the actors in this exhibition, for whose benefit a priest with holy water is in regular attendance. Not less is the fondness for the dance, particularly under its national forms of the *fandango* (*fig. 266.*), the *bolero*, and the *guanacho*, performed with the castanet in the hands; and the two former especially consisting chiefly in movements expressive of passion, but so little consonant to the rules of decorum, that the indulgence shown to these amusements by the church cannot but be regarded as matter of surprise.

2472. *The dress of the Spaniards* is antique, and varies much according to the different provinces; that of the ladies consists chiefly of a petticoat and a large mantilla or veil, covering the upper part of the person. The grandees, and the opulent in general, display a profusion of jewels; the dress of the men is slight, and closely fitted to the body, with the exception of a loose cloak thrown over the whole. The minister, Squillace, under Charles III.,

having conceived that these cloaks, by concealing the person, served as a cover to deeds of violence, stationed persons at the corners of the streets, who seized the passengers, and forcibly cut down this part of their dress to the legal dimensions; but this measure raised so violent and general a clamour, that the king was forced to appease it by the sacrifice of the minister who had attempted such an obnoxious curtailment.

2473. *Both in eating and drinking* the Spaniards are temperate; the only noted national dish is the *olla podrida*, in which various meats, vegetables, and herbs are mixed together in a manner which even foreigners admit to be palatable. The pleasures of society are chiefly sought at *tertulias*, or evening parties, where only slight refreshment is presented; but *refrescos* or dinner parties are given on a large scale upon very special occasions.

SECT. VII. Local Geography.

2474. *Of the divisions of Spain*, the most prominent is into kingdoms or principalities, each of which, at some period of its eventful history, enjoyed an independent existence, though they are now merged into one monarchy. More recently the country has been split into a number of smaller departments or jurisdictions; but the original distinction into kingdoms, being founded upon natural limits, and maintained by feelings and impressions derived from former independence, is still the most interesting. The kingdoms are New Castile, Estremadura, Old Castile, Leon, Galicia, Asturias, Biscay, Navarre, Catalonia, Aragon, Valencia, Murcia, Granada, and Andalusia.

2475. *The following table* exhibits the divisions and subdivisions of Spain, with the extent and population of each, according to Hassel:—

		Square Leagues.	Popu- lation.			Square Leagues.	Popu- lation.
New Castile	Madrid	110	298,000	Asturias		3082	565,000
	Toledo	734	485,000	Galicia		1330	1,585,000
	Guadalaxara	163	153,000	Catalonia		1003	1,116,000
	Cuença	945	362,000	Navarre		205	288,000
	La Mancha	631	257,000			106	145,000
Estremadura		1199	556,000	Biscay	{ Biscay	52	136,000
		642	612,000		{ Guipuscoa	902	93,000
Old Castile	Burgos	341	267,000		{ Alava	12,322	856,000
	Soria	290	221,000	Aragon		643	1,255,000
	Segovia	215	153,000	Valencia		659	493,000
	Avila	493	311,000	Murcia		805	1,097,000
Leon	Leon	145	153,000	Granada		752	970,000
	Palencia	165	126,000	Andalusia	{ Seville	268	277,000
	Toro	271	243,000		{ Jaen	348	325,000
	Valladolid	133	93,000		{ Cordova		
	Zamora	471	273,000				
	Salamanca						

2476. *With New Castile*, the central and metropolitan province, we commence our survey: it consists chiefly of an extensive plain enclosed between two of the long parallel mountain ranges, the Sierra de Guadarrama and the Sierra de Toledo. Along this plain, and parallel to both ranges, the Tagus flows in a deep rocky bed. Beyond the Sierra de Toledo, the district of La Mancha, which we include also in New Castile, extends to a third parallel mountain range, the Sierra Morena, dividing it from Andalusia and the southern provinces. The plain of Castile Proper is elevated and naked; and being thus exposed to the sun's direct rays, presents a bare and parched appearance. It includes, however, fertile valleys, producing wine, oil, grain, and fruits of various kinds; but the inhabitants are extremely deficient in every species of industry.

2477. *Madrid* (*fig. 267.*), the capital of Castile, and of "all the Spains," stands on several low hills on the immense Castilian plain, which on the north appears bounded by the high distant range of the Guadarrama, but on every other side has no visible termination. A small rivulet, the Manzanares, flows past the city, and falls into the Tagus. Madrid is a superb but somewhat gloomy capital; the houses are high, well built of good stone, not defaced by

smoke; the streets are well paved, and have broad footpaths. The main street of Alcala, long, spacious, and bordered on each side by a row of princely houses, attracts particular admiration. The Prado, a wide public walk, bordered by trees, and connected with gardens all open to the public, is equally conducive to ornament and pleasure. There are many public fountains, supplied with pure, light, and salubrious water, filtered through beds of gravel and sand, from a distance of seven or eight leagues. The gates built by Charles III., are uncommonly beautiful, particularly that of Alcala; though Mr. Semple criticises their position in a miserable wall which might be battered down by a three-pounder in half an hour. The royal palace, built by Philip V., is a spacious and magnificent structure, though the taste displayed in it is a subject of controversy. It contains numerous fine paintings, though not equalling those of the Escorial. The Retiro with its fine gardens, was defaced by the French, who made it a military post; an extensive and costly menagerie, however, is now forming within its precincts. The museum of statuary and painting, a new and elegant building, has recently been enriched with some of the finest pictures from the royal palaces. The cabinet of natural history, supported by the government, is also a handsome structure, and its contents valuable. The environs of Madrid are not remarkable for beauty; they are much broken into hills and hollows; so that, of the 200 villages situated in them, only three or four can be seen at once.

2478. *Toledo*, even in its present decay, excites an interest equal or superior to Madrid. Once the proud capital of Spain, it has a commanding site on a lofty rock, almost insulated by the Tagus. A position so strong rendered it a grand national bulwark during the long ages of internal warfare, but occasioned its desertion during peace, when it was felt as extremely inconvenient, the streets being so steep that a carriage can scarcely drive safely through them. Its manufactures of wool and silk, which are said once to have employed nearly 40,000 men, have disappeared; and government has in vain attempted to revive that of swords, of which those formerly manufactured at Toledo were valued above all others. Its population of 200,000 has been reduced to 25,000; and it presents a mere mass of narrow, deserted, winding, and dirty streets. Toledo, however, still exhibits two grand monuments; the Alcazar or palace, and the cathedral. The former is a noble and extensive pile, in a pure style of architecture, and the granite columns of the Corinthian order which adorn the inner court are particularly admired. The grand staircase and spacious gallery, no longer crowded with guards and courtiers, are now dirty, deserted, and silent. This edifice, however, though neglected and decaying, still wears a stately and imposing aspect; "and its handsome front, immense quadrangle, and elegant colonnade, declare it to have been the pride and ornament of a happier period." The cathedral is also one of the grandest edifices in the Peninsula. It was originally a mosque, built in a grand style; but its simplicity has been much impaired by tasteless additions, and by the profusion of gilding, relics, and statues, with which its interior has been filled. It retained its wealth and splendour, however, till the late war, when its treasures became the prey of the invader, and its six hundred ecclesiastics were dispersed, leaving only a few to perform the sacred functions.

2479. *Two other considerable towns* in New Castile are Guadalaxara, to the west of Madrid, where the government has established a manufacture of fine cloth on a great scale. It is of course an ill-conducted and unprofitable concern; yet it supports the population of 12,000 or 14,000 in a degree of comfort not usual in Spanish towns. To the east, Cuenca is the capital of a mountain district of the same name, interposed between Valencia and the plain of Castile. It is a small ancient city, distinguished by a cathedral and some other monuments.

2480. *La Mancha*, sometimes reckoned a separate province, is the most southern part of Castile, from which it is separated by the Sierra de Toledo. It is an immense table plain, intersected by different ridges of low hills and rocks, without a tree, except a few dwarf evergreen oaks; or an enclosure, except mud walls round the villages. All this vast tract of open country is cultivated, and produces corn or vines: its wine, especially that of Val de Peñas, enjoys a high repute. Its name, however, is chiefly familiar to the public as having given an appellation to the celebrated hero of Cervantes. The names of Don Quixote and Sancho Panza are familiar to the district; and the dress of the peasantry presents still an exact model of that of the doughty squire. There are a number of large villages; and Ciudad Real, the capital, is well built in a fine plain, though it has lost much of its former prosperity. Almagro and Ocaña are also pretty considerable towns.

2481. *Estremadura* forms a continuation to the west of the same plain as New Castile, traversed like it by the Tagus, and bounded by the same ranges of mountains. It is a fine, wide, wild province, diversified by rugged mountains, deep valleys, and almost boundless plains. The depopulation generally complained of in Spain seems more remarkable here than in any other province; and vast tracts may be passed without seeing a human habitation. This seems chiefly owing to the pernicious laws of the Mesta, which assign it almost entirely for the occupation of the merino flocks, when they descend from the mountains of Leon. Estremadura, therefore, forms a vast pastoral district; only a small proportion of its surface being necessary to furnish grain for its scattered population. Yet

the Romans made it one of the chief seats of their dominion ; and no part of the Peninsula exhibits more striking works and monuments of that great people. The Estremenos also retain much of the antique Spanish aspect and character ; and no province, during the late crisis, made more striking displays of patriotic energy.

2482. *The cities* are no longer considerable. Badajos, the capital, a strange corruption of the Roman name Pax Augusta, is a considerable and strong town, but much shattered by the successive sieges it sustained in the late war from Soult and Wellington. Merida, the ancient capital of Lusitania, excites more interest, from the striking remains which it presents of Roman magnificence. The amphitheatre, baths, a lofty triumphal arch, three votive altars, and a handsome stone bridge, are all magnificent monuments, and in wonderful preservation. Truxillo, an old city, of small extent, was the birth-place of Pizarro, whose splendid mansion is still to be seen, adorned with barbarous trophies of his conquest. Almaraz is distinguished chiefly by the very noble modern bridge adjoining to it. Talavera de la Reyna, once splendid but now decayed, has acquired recent lustre from being the theatre of one of the greatest battles fought during the peninsular war. In the extensive plain north of the Tagus are the two pleasant little cities of Coria and Placencia ; the latter of which was the scene of the singular monastic retirement of Charles V. In the mountains separating this part of the province from Leon is a rocky region, of the most savage and desolate character, called the Batuecas.

2483. *Old Castile* is situated on the opposite side of the chain of mountains which forms the northern boundary of New Castile. It presents a high variegated table-land, separated on the north by the Cantabrian chain from Asturias. Some parts are rugged ; but it is, upon the whole, a fertile well-watered region, traversed by the Duero in its early course. There are many tracts of rich pasturage, and others equally fitted for the growth of corn. It is, however, one of the provinces in which the marks of decay are most striking. The capitals are neglected and ruinous ; large portions are left uncultivated ; and of the fine manufactures of cloth from the merino wool, only a remnant is now supported by the aid of government. Castilian pride and indolence have fixed here their old and central seat : the hidalgos belonging to Old Castile amount to 146,000, a much larger proportion than in any other province.

2484. *Burgos*, the once magnificent capital of the kings of Castile, and the highest in rank of any city in the kingdom, is dwindled into a poor place, not containing above 10,000 inhabitants. Amid its gloomy and decayed streets, however, towers the cathedral, one of the finest specimens of Gothic architecture existing in Europe, and the form of which bears a considerable resemblance to that of York minster. The strong ancient castle, which had fallen into decay, was, however, so far re-established by the French, that it successfully stood a long siege from the Duke of Wellington.

2485. *Of the other towns* of Old Castile, Segovia presents some interesting monuments of

268

AQUEDUCT OF SEGOVIA.

Roman and Moorish grandeur. Its aqueduct (*fig. 268.*), of 159 arches, nearly half a mile long, and in one place 94 feet high, is a stupendous Roman work, ranked by Swinburne above the Pont du Gard. The Alcazar, or royal castle, was erected by the Moors on a rock overlooking a wide range of country. After it came into the possession of the Christians, it was employed as a state prison, and is now a military school. Five centuries ago, Segovia had

very extensive manufactures of fine cloth ; but these, notwithstanding the honour of having the king for a partner, have dwindled to a very small amount. Avila, capital of a small province of the same name, is a city of ancient distinction ; and its massy walls, its towers, its Alcazar, and the dome of the old cathedral, render it imposing at a distance ; but it is in a state of wretched desertion. The attempt to establish manufactures of cloth and cotton has not been successful. Soria, near the site of the ancient Numantia, on the right bank of the Duero, near its source, is a tolerable country town, capital of one of the smaller provinces into which Old Castile has been subdivided.

2486. *The palaces* of the Escorial (*fig. 269.*) and San Ildefonso are striking objects in Old Castile. The "royal monastery" of the Escorial was founded by Philip II. on a plan entirely congenial to his gloomy mind. It unites the characters of a palace and a convent ; and has the form of a gridiron, the instrument of the martyrdom of St. Lorenzo, to whom it is dedicated. Attached to it is the Pantheon, a classic and somewhat profane structure, in which, however, are interred all the crowned kings and queens of Spain since Charles V.

The wealth of the Spanish monarchs has been continually employed in adding new ornaments to this favourite residence, which is considered by the nation as the eighth wonder of

ESCURIAL.

the world; and large volumes have been filled with descriptions of it. The church and the great altar have scarcely a rival for magnificence and grandeur of effect. The library is not extensive, but contains manuscripts, especially Arabic, that are of great value. The collection of paintings, it is probable, yields only to that which covers the walls of the Vatican. Besides select productions of Murillo and other masters of the Spanish school, it

contains several of the greatest works of Raphael, Titian, and others of the first Italian masters. The environs are wild and naked in the extreme, without shelter from the cold blasts of winter, or the intense heats of summer. On the opposite declivity of the same mountains, looking towards the north, San Ildefonso, without any pretensions to equal magnificence, is finely surrounded by woods, gardens, and beautiful jets d'eau. Aranjuez stands in quite a different situation, on the lowest plain of Castile, at the junction of the Tagus and the Xarama. It is chiefly admired for its magnificent woods and gardens; the former carried in long and spacious avenues, the latter containing in profusion the finest native and exotic plants.

2487. *Leon* forms a continuation of the plain of Old Castile, along the lower course of the Duero, and bounded by the same ranges of mountains. For several centuries it was the seat of a kingdom, comprising the chief Christian power in Spain, until it was united to that of Castile. It is almost entirely within the domain of the *mesta*, and thus devoted principally to pasturage. The consequent depopulation has been very great; insomuch that, according to Townshend, the bishopric of Salamanca, which once contained 748 townships, is now reduced to 333. The vast extent of open plain which forms the centre of this province has been found highly favourable to an invader who possessed superior cavalry; such as the Moors once, and more latterly the French.

2488. *The cities of Leon* are almost solely interesting from the traces which they present of ancient grandeur. Leon itself, by its highly ornamented cathedral, its nine convents, and its ancient palace, testifies the remote period when it was the seat of royalty; but a heterogeneous assemblage of dirty streets filled with beggars, splendid churches, and half ruined family mansions, are all that it now presents. Salamanca, by its university, has acquired a much greater fame. This seminary, one of the first in Europe, was founded in 1200, and extended during the same century by Alfonso the Wise, celebrated for the progress which astronomy made under his auspices. From the medical knowledge of Avicenna, Averroes, and other Arabian sages, it derived a character superior to those of the other monkish universities during the middle ages. Salamanca, however, remained stationary in the fourteenth century; and, while sound science was spreading through the rest of Europe, continued to occupy its students with dogmatic theology, and with the worship of Aristotle and Aquinas. Its students, once reckoned at 16,000, have been reduced to less than 2000. Salamanca is crowded with sacred edifices, to enrich which, all the four corners of the world have been made to contribute; and on days of high festival the display of silver and precious stones was altogether dazzling. The cathedral and the principal square are very magnificent, but the streets are narrow and gloomy. Captain Sherer, in 1813, found Salamanca quite a deserted city; only a few of the old professors and youthful students still lingered in the colleges, or paced the spacious aisles of the elegant cathedral. Of the latter, some, as appears from Mr. White, notwithstanding the antiquated course of instruction, had adopted modern and liberal ideas, and in the late crisis obeyed the call of their country and of liberty. The French having made Salamanca a military position, a great part of the place was levelled or battered down; and subsequent events have not been favourable to its restoration. We must not, however, dismiss Salamanca without noticing the new lustre it has derived from giving name to one of the most splendid of Wellington's victories.

2489. *Valladolid* has a great name in history. Charles V. made it his capital, and it continued to be the residence of the Spanish court until Philip IV. removed it to Madrid. In these splendid days Valladolid was supposed, perhaps with some exaggeration, to contain 200,000 inhabitants, now reduced to a tenth of that number. Yet it covers a very large space of ground; and the numberless spires, domes, and turrets of its sacred edifices give it still the appearance of a large metropolis. Its university is attended by 2000 students, and taught by forty-two professors and fifty doctors. After a very marked period of decay,

Valladolid experienced lately a considerable revival. Its environs are particularly healthy and agreeable.

2490. *Several other large decayed towns attest the former grandeur of Leon.* Zamora and Toro, both on the Duero, are capitals of two of the small provinces. Benavente is distinguished by its castle, which has been described as one of the grandest monuments of the age of chivalry; and Tordesillas was a royal residence in the reign of Charles V. Astorga, once capital of the Asturias, and one of the bulwarks of the Peninsula, has lost its strength and magnitude. Palencia is also a small capital, pleasantly situated on the Carrion, having a little inland trade. Ciudad Rodrigo is a national barrier on the Portuguese frontier, still kept up as a strong fortress, which sustained successive sieges during the peninsular war.

2491. *Galicia*, separated by its mountain boundary from Leon, forms the south-western corner of the Peninsula. It is entirely a highland and alpine region, broken into rugged rocks and narrow passes, though with valleys of great fertility and of peculiar beauty interspersed. The Gallegos are industrious; and the country is better peopled than many of the more favoured regions of the Peninsula. They are hardy and enterprising, and often leave this barren territory to seek employment in the cities of Spain and Portugal, where, like the Scottish highlanders, they act chiefly as porters and servants. The shores and ports of Galicia are celebrated in naval history, forming as it were the outer coasts of Europe, beaten by the waves of a tempestuous ocean, and where fleets from the distant quarters of the globe often made their first appearance in Europe, and met with hostile fleets on the watch for them.

2492. *The interior towns of Galicia* have for their capital, St. Jago de Compostella, the most celebrated shrine of the Peninsula, supposed to contain the body of St. James, its patron. In the chapel dedicated to him is his statue, two feet high, of pure gold, illuminated every night by 2000 wax tapers. Twenty-two other chapels have been enriched by the offerings of pilgrims from every part of the Peninsula, whose numbers have diminished. Lugo presents the poor remains of an ancient city surrounded by a wall and towers, once of great strength, but now mouldering into ruin. Orense, a little city, formerly celebrated for its hot springs, and Tuy, a strongly situated fortress, are on the Portuguese frontier.

2493. *Of the seaports of Galicia*, Vigo had the greatest reputation, several great naval actions having been fought near it; particularly that of 1702, when the whole fleet of Spanish galleons was sunk or taken by the English. It has one of the finest harbours in Spain; which, however, since Ferrol became the chief naval station, is only employed for a limited coasting trade. Corunna on the Groyne is now the most trading place in the province, and packets sail from it to England and America. It is a steep, dirty, but well-paved town, of no strength, being commanded by the neighbouring heights. Ferrol, since 1752, has been made the chief naval station of Spain. Its harbour, besides being one of the safest and most spacious in Europe, has the advantage of being accessible only by a narrow winding passage which can be rendered almost impassable by a chain of forts. A considerable city has been formed, and very extensive docks and arsenals built; but since the extinction of the Spanish navy, these have of course fallen into considerable neglect.

2494. *The Asturias* form a long narrow stripe between the Bay of Biscay and the Cantabrian mountains, which extend along its whole length. It is celebrated in history as the sacred retreat in which the hero Pelayo raised again the national standard, after it seemed for ever trampled under foot by the Saracen invaders. Since the fourteenth century the Asturias have given the title of prince to the heirs of the Spanish throne. The province is approached only by narrow ravines and passes, through which torrents dash, and which are overhung by steep cliffs and luxuriant woods. There are, however, a number of valleys, and the whole plain of Oviedo is distinguished both for fruitfulness and beauty. Instead of wine, a good deal of tolerable cider is made and exported: amber, jet, and coal abound, but the last strongly impregnated with sulphur. The Asturians are brave and proud, boasting that their country was never conquered, even by the Romans; and more than a third part of the population is composed of hidalgos.

2495. *Oviedo*, the only large town, has more magnificence than its situation might lead us to expect: the cathedral, in particular, long the only shrine secure from the rage of the invader, afforded an asylum to many pious treasures scattered through the Peninsula. These, however, consist chiefly of relics, valuable only to devout and believing eyes. Among them are the rod of Moses, the mantle of Elias, the olive branch borne aloft in entering Jerusalem; thorns from the sacred crown; the milk of the blessed Virgin, &c. Oviedo is still a considerable town, with a rich bishopric, and many religious houses; the principal is a convent of Benedictine nuns, the revenues of which, however, do not, according to Townshend, exceed 2100*l.* a year. Gijon, though with a costly and not very complete harbour, carries on all the little trade of the province. Avila and Santillana are large villages, giving their name to districts. Santander and Santona are sea-ports of some little consequence, in the district of Montana, on the borders of Biscay.

2496. *Biscay* is a small, high, rugged province, on the western slope of the Pyrenees. Streams descending from its numerous heights, combine in forming the channel of the Upper

Ebro. The Basques are a peculiar race, preserving the only remnant which revolutions have left in the Peninsula, of Celtic language and aspect. Under the name of Cantabria, this region presented a barrier even to Roman conquest; and though the Saracens penetrated through it into the plains of France, it is still boasted that they never could reach the mountains of High Cantabria. The Basques, amid the general slavery of Spain, have still preserved some portion of their original rights. They have a cortes of their own; and the taxes, levied by provincial authority are presented to the sovereign in the form of a free gift. Every native Biscayan is an hidalgo or noble, scarcely owning a superiority of birth in the proudest Castilian. With all this they are excessively industrious; the mountain declivities are cultivated as high as the plough can reach; and while the finest plains of Castile are nearly a desert, Biscay's rude vales are covered with a numerous population.

2497. *The cities* in such a district cannot be large: yet Bilboa, the capital, situated on the Ybaizabal, which admits large vessels up to the town, is one of the most commercial places in Spain. Most of the merino wool from the plains of Castile is brought hither for exportation. Biscay Proper contains also Orduña, a neat little city, and numerous villages. Guipuscoa is another district, lying more to the east, and in closer contact with France. Its capital is St. Sebastian, an indifferent port, but a neat, tolerably large city, and so strongly fortified as to be considered one of the four keys of the kingdom; the others being Pamplona, Barcelona, and Figueras. Fontarabia, close to the frontier, has a great name in history, but little else now left. The small village of Irun stands on the immediate bank of the Bidassoa, whose broad clear stream, descending from the Pyrenees, forms the boundary between two rival and long hostile nations. More in the interior, and on a lower level, is the district of Alava, having for its capital Vittoria, a somewhat well-built modern town, and celebrated as the theatre of the complete victory there gained by the Duke of Wellington over the French army under Joseph Bonaparte, which was thence finally expelled from the Peninsula.

2498. *Navarre* is a small province or kingdom, lying immediately beneath the highest and steepest Pyrenees. Eight very difficult passes penetrate through them into France, but scarcely any one passable for the artillery and train of an army. The principal is that of St. Jean Pied de Port; on the French side of which is Roncesvalles, or Roncevaux, celebrated in history, and still more in romance, for the disaster which there befell Charlemagne and his knights. For many centuries it formed a separate little kingdom connected with France, until Ferdinand the Catholic succeeded in annexing to Spain all the part south of the Pyrenees. Navarre retains, however, privileges and customs peculiar to itself, and its governor bears the title of viceroy. The population is active, hardy, and brave. The bands of guerrillas under Mina proved the most formidable irregular force with which the French had to contend in the Peninsula. Pamplona, the capital, the foundation of which is ascribed to Pompey, is one of the chief bulwarks of the Peninsula, and one of the strongest fortresses in Europe. It was reduced by the Duke of Wellington, and by the French, in their last invasion, after a long blockade. There are also Tudela and Calahorra, little towns on the Ebro.

2499. *Aragon*, south from Navarre, is an extensive province, extending along the greater part of the course of the Ebro; whence it reaches on one side to the Pyrenees, and on the other to the chains which shut in the Castiles and Valencia. A great part of it is rugged and barren; though other tracts in the central plains, and along the rivers, are very susceptible of culture. Aragon, during the middle ages, was a powerful kingdom, comprising Catalonia and Valencia, forming the half of Christian Spain, then divided between it and Castile. Even after the union of the crowns under Ferdinand and Isabella, it still enjoyed its constitution and its cortes, which exercised higher prerogatives, and kept the power of the kings under stricter limitations, than any similar assembly in Europe. Of these it was deprived by the unfortunate issue of the civil war under Charles V., and more completely by the Bourbon succession, after Aragon had espoused the cause of Charles of Austria. The peasantry of this province are a fine body of men, stout, brave, and honest. Culture and population are generally in a backward state; yet the canal of Aragon, conducted parallel to the course of the Ebro, though it has not yet reached the sea, according to its destination, has given a considerable impulse to the agriculture of the district through which it is led.

2500. *Saragossa*, or *Zaragoza*, the capital of Aragon, is a large and celebrated city, situated amid a fine plain, on the banks of the Ebro and of the canal of Aragon. From Augustus, who enlarged and improved it, the city was called Cæsar-Augusta, corrupted into Saragossa. It is not well built, the streets being narrow and crooked; but there are several open market-places, and some very splendid religious edifices. The principal is that dedicated to the Virgin, under the title of "Our Lady of the Pillar;" an object of the most profound veneration to the citizens, and enriched by offerings from every part of Spain. The church of St. Engracia is also filled with relics and gifts; and each of the forty convents of Saragossa has its peculiar boast. A stone bridge, and the finest wooden bridge in Europe, are thrown over the Ebro. The university has 2000 students, but not much literature. Saragossa has earned an immortal name by her heroic resistance against the unprincipled in-

vasion of Napoleon, in 1808. Without walls, except an old one of earth, which could not resist for an hour an attack conducted on modern principles; without army, arms, or artillery, it maintained a long and finally successful conflict with the French, in their first invasion. Afterwards, when assailed by an immense and overwhelming force, the flower of the French armies, without hope of relief, it made a mighty resistance; and it was only by mining operations, blowing up successively house after house, that the French finally became its masters, after having reduced it to a heap of ruins.

2501. *Aragon has some other small ancient towns*, ranking even as cities; Jaca and Huesca on the northern frontier among the Pyrenees, both episcopal seats; Daroca and Calatayud in the plain bordering on Castile; the former enclosed with large ruined fortifications, the latter industrious, and surrounded by a smiling country.

2502. *Catalonia*, to the east of Aragon, is one of the finest and most extensive provinces of Spain. It presents a remarkable variety of surface, from the steep and rugged heights of the higher Pyrenees, to the elevated valleys of Upper Catalonia, and the luxuriant though not very extensive plains that border on the Mediterranean. The Catalans redeem to a great extent the Spanish national character, uniting with its loftiness and energy a spirit and activity which are elsewhere wanting. They have been always commercial, industrious, and fond of liberty. After bearing successively the yoke of the Romans, the Goths, and the Saracens, Catalonia was long ruled by counts of French descent, whose posterity extended their sway over Aragon, and finally over the whole Peninsula, in which this principality merged. The Catalans, however, bore more impatiently than other Spaniards the loss of their privileges; and during the war of the succession, on receiving a pledge for their restitution, espoused with extraordinary ardour the cause of the Archduke Charles. Even after its unfortunate issue, when deserted by Britain and all the other powers, they made a last dreadful struggle, which ended, however, in the loss of all those rights for which they had so nobly contended. In the last two wars, Catalonia acted a most conspicuous part; maintaining an unremitted resistance to France, notwithstanding the close vicinity of that kingdom, and in the late constitutional struggle making efforts, both for and against liberty much greater than any other province.

2503. *Barcelona* is, after the capital, the largest city, and at the same time the most industrious and flourishing, of all Spain. It is situated about the centre of the Catalonian coast, and draws its subsistence from a fertile and extensive plain behind. It is said to have been originally a Carthaginian town, founded by Hamilcar Barcas; but rose to little distinction under the Romans, who made Tarraco the capital of all eastern Spain. It was not till the twelfth century that Barcelona began to be distinguished for its commercial spirit. It suffered severely during successive wars, particularly that of the succession; but in the course of the last century, the exertions of its patriotic governor, the Marquis of Mina, enabled it to retrieve all its losses, and become more prosperous than ever. The port is artificial, formed by solid and convenient moles, but has a bar at its entrance, which excludes vessels drawing more than twelve feet of water. It carried on a great and various traffic; had woollen, silk, and cotton manufactories, all on a considerable scale; about a thousand vessels annually entered its port; and the whole amount of exports was reckoned by Laborde at 1,750,000*l*. According to the latest account, however, by the author of "A Year in Spain," the late disasters and misgovernment have caused a great declension in the above branches of manufacture; and instead of the ranges of tall masts assembled within its mole, there are to be seen only a paltry assemblage of fishing-boats and feluccas. The ecclesiastical edifices of Barcelona are handsome, particularly the cathedral, though not of so grand a character as those in some other parts of Spain. The convent of the Dominicans has a singular series of ornaments, the sentences of five hundred heretics decreed by the Inquisition, and under each sentence a representation of the sufferer, whom the demons, in various shapes, are torturing and devouring. The walls of Barcelona are strong, but its chief dependence is upon the citadel of Montjuich, which commands it, and is considered almost impregnable, though the Earl of Peterborough took it by surprise. At the close of the war of the succession, when Barcelona was besieged by the Duke of Berwick, a terrible and almost frantic resistance was made in the streets, not by troops, but by priests, students, tradesmen, and even women: the consequences were terrible. Bonaparte, in 1808, obtained by treachery and threats the cession of this and the other keys of the kingdom; but in the late invasion, its resistance against Moncey was most gallant.

2504. *There are several other large, ancient, and strong towns in Catalonia*. Tarragona, the Roman capital of the east of Spain, has fallen into great comparative decay. It is situated on a rocky peninsula, and presents many traces of Roman antiquity, as of the palace of Augustus, the amphitheatre, and an extensive aqueduct. More recently, the harbour has been improved, and some new streets built; and in the war of 1808, the fortifications were restored, and the city made a brave defence against Marshal Suchet, who at length carried it by storm, with circumstances of great cruelty. Tortosa is also a considerable and ancient city near the mouth of the Ebro, which is there broad and navigable. It made a distinguished figure during the wars with the Moors, chiefly through the exploits of its

heroines, to commemorate whose valour a military order was instituted by Raymond Berenger. Its position on the river affords scope for a considerable trade; and during the last war its fortifications were restored by the Spaniards. Between the two last-mentioned cities has arisen, within the last half century, Reus, a large flourishing industrious town, carrying on various manufactures, particularly of brandy and leather. All these are on the coast west of Barcelona. To the east the chief place is Gerona, a large gloomy town, in a fine situation. It is well fortified; and its resistance, protracted for more than half a year, to the unremitted efforts of Bonaparte's generals, formed one of the most glorious events of the peninsular war. Rosas, a little town, prettily situated in a fine bay, exports cork and other timber. In the interior, Lerida, distinguished as a Roman station under the name of Ilerda, is a large and strong town, situated in a most delightful country on the banks of the Segre. A considerable stand was made here by the patriotic armies during the French invasion. Mequinenza, at the junction of the Segre with the Ebro, is also an important military post. Cervera, the seat of a considerable university, and Igualada, are pretty large interior towns, supported by the produce of the rich vales in which they are situated. But the most striking feature in all Catalonia is the single, lofty, and precipitous mountain of Montserrat (*fig. 270.*). It consists of a crowd of conical hills piled over each other, broken

MONTSERRAT.

into steep walls of white and variously tinted limestone cliffs, the interstices of which are filled with evergreen and deciduous trees and plants. The Benedictine monastery, an ancient and remarkable structure, stands on a cleft at the top of a high rock, where space is scarcely left for the edifice, while far beneath roars the Llobregat. Numerous hermitages pitched on the top of precipices, or in cavities hewn out of the rock, increase the singular and romantic appearance of the scene.

This mountain, in the last war, was converted into an almost impregnable military position. On the highest of all the Catalonian vales, which is extensive, and rich in grain, stands Urgel, a small episcopal see, and a strong military post, the roads being almost impassable to artillery.

2505. *Valencia*, beginning from the border of Catalonia and Aragon, occupies an extensive coast running from north to south, and is the first of the southern provinces. The plain ranks as the garden of Spain, and almost of Europe. The fields of corn; the yellow green of the mulberry plantations, the pale hue of the olive; the woods, villages, and convents, thickly scattered over this great expanse, with numberless slender steeples, present, when united, an inimitable landscape. The country is finely watered by the Xucar, the Guadalaviar, and other rivers, numerous though not of long course. A great extent of artificial navigation was formed by the Moors, and is still kept up, though not in a very complete state. The province yields, in abundance, the usual products, corn, wine, oil, silk; with rice enough to supply the greater part of Spain, and barilla for exportation. The Valencians are very industrious, and of a gay disposition. Colonies from the south of France, introduced by the first Christian conqueror, brought with them a portion of the spirit of that nation.

2506. *Valencia*, at the mouth of the Guadalaviar, is one of the largest and most flourishing towns of the kingdom. It is of Roman origin, but its fame dates from the eleventh century, when it was conquered by the Cid from the Moors, and ruled as a fief by that greatest of the Spanish heroes. It was the scene, however, of long-continued contest; and its final annexation to Christian Spain did not take place until a century and a half later. The lofty walls and towers of Valencia are now nearly demolished, and in the war of liberty neither it nor the province made any very conspicuous figure. The silk manufacture is one of the most extensive in Spain, though checked by an absurd prohibition against the exportation of its produce. In a levy during the late war, exemption was granted to upwards of 3000 silk-weavers, that the trade might not be interrupted. There are also manufactures of woollens and paper. The Grau, or port of Valencia, is only an indifferent roadstead, and the commerce not nearly equal to that of Alicant. The city, though large and rich, is not handsome; the streets being narrow and winding, and bordered by high old houses. The churches and convents are of course numerous, and many of them richly ornamented, but none very prominent in architectural beauty. They are adorned, however, with numerous pictures by some of the most eminent Spanish painters, natives of Valencia; Juanes, Ribalta, and others, whose works are unknown in this country, but are admired by those who have visited Spain. The religious festivals of Valencia are celebrated with a childish pomp, in some degree disused in other parts even of this country. On these occasions, all the most memorable events and most illustrious characters in scripture history are

represented either by figures in wicker-work, or by citizens fantastically attired. The exhibitions of this kind, amounting annually to a hundred and fifty, give great occasion to idleness and dissipation; yet the attempts to reduce their number have been hitherto unsuccessful.

2507. *Alicant*, situated at the bottom of a bay on the southern frontier, ranks high as an industrious and commercial town. Its prosperity is modern, chiefly owing to the refuge which its lofty castle afforded from the dreadful irruptions of the Barbary corsairs. Even since this danger ceased, Alicant has continued to be a fortified town; and none of the invading armies in the late war were able to obtain possession of it. About 1000 vessels annually enter its port, and are loaded with barilla, raisins, and a small quantity of wine and brandy. The import from England consists chiefly of salt-fish, the great article of consumption in Catholic countries. The herring and other fisheries are carried on with considerable activity on this coast. They are encouraged by the government, but with an absurd limitation to a body of enrolled fishermen, amounting to about 16,000.

2508. *Among other important towns* may be mentioned Elche and Orihuela, large and flourishing places, in the very finest part of the plain of Valencia. Segorbe and Liria are pleasant interior towns towards the frontier of Aragon. San Felipe, under the name of Xativa, made a distinguished figure in the war of the succession; when, after being demolished, it was rebuilt by Philip V. under its present name. Denia and Gandia in the south, and Peñíscola in the north, are sea-ports on a smaller scale. But all these places yield in ancient fame to Murviedro, occupying the rocky site of the ancient Saguntum, the siege of which formed the commencement of the career of Hannibal. The long resistance of this powerful and unfortunate city forms the first of the many remarkable sieges which have distinguished the Spanish annals, ancient or modern. The Romans restored and made it a great colony, and the Moors erected a range of fortifications on the summit of the hill; so that its mountain site is now covered with ruins of various dates and descriptions. Half-way up the eminence, the outline of a theatre capable of containing 9000 persons may still be traced; and a few ropemakers plying their trade alone break the silence of this august ruin. Murviedro is a small town still fortified, though the resistance made by it in the last war was not formidable.

2509. *Murcia* is a small province, partly bounded on the south-east by the coast, which here changes its direction from southerly to westerly. Its vale is almost without a rival for beauty and fertility, even in southern Europe. Its natural fruitfulness is greatly aided by the numerous canals of irrigation which the Moors drew from the river Segura. These advantages are little improved by the present inhabitants, who are noted as exhibiting, in a peculiar degree, all the blemishes of the Spanish character; its pride, its bigotry, and its laziness. Even the song and the dance do not inspire gaiety in its vales, as in all the rest of Spain; almost the whole time of the people being spent in eating, sleeping, and making cigars. A sullen and vindictive spirit is said to lurk under this outward apathy. Few Murcians have made a figure in literature, in the arts, or in public life.

2510. *The cities of Murcia*, if we except its port of Carthage, do not merit particular notice. The capital, bearing its name, is an irregular, ill-built, ill-paved large town. The ecclesiastical edifices, however, are very costly, and the front of the cathedral, according to Mr. Townshend, produces a splendid effect with its sixteen Corinthian columns of marble, and thirty-two images as large as life. The interior does not possess equal elegance, but is chiefly distinguished by the proportion of gold, silver, and jewels, not to mention the relics, which are accounted by the faithful as of much superior value. Lorca is a large town, built with some elegance, and surrounded by fine promenades. It had extensive fabrics of silk and saltpetre, which were reviving, when a singular accident arrested their progress. A speculative individual had collected all the waters of the neighbourhood into an immense reservoir, whence he supplied them to the cultivators for purposes of irrigation; but this

receptacle, not being fully secured, burst at one point, destroyed part of the suburbs of Lorca, desolated a great extent of country, and reached even Murcia. Totana, a populous village, is enriched by the copious production of barilla in its neighbourhood. The castle of Almanza (*fig. 271.*), picturesquely seated on a height, is celebrated as the spot near which, in 1707, was fought the celebrated battle which decided the Spanish succession in favour of the house of Bourbon.

ALMANZA.

2511. *Carthage*, situated in Murcia, though scarcely belonging to it, forms one of the few great Spanish emporia. This celebrated capital of ancient Spain was founded by Asdrubal; and when taken by Scipio, in the year of Rome 550, was considered one of the most

opulent cities in the world. It was nearly destroyed by the Vandals, but was restored by Philip II., and has ever since continued to flourish. It enjoys one of the finest ports in Europe, consisting of a bay sheltered by high mountains from almost every wind. The staples are the same as at Alicant. The revenue, raised by a small though impolitic duty on the export of barilla, amounts to 25,000*l*. The fishery is also considerable. There are few Murcian residents, and the trade is carried on chiefly by English, French, and Italian houses. The streets are wide, and the houses agreeable, with terraced roofs, commanding a view of the sea; but neither here nor at Alicant are there any structures, even ecclesiastical, at all worthy of notice.

2512. *Andalusia*, taken in its most comprehensive sense, is the largest of the Spanish provinces, and, we may add, the finest and most remarkable, both as to nature and art. The Guadalquivir, with numerous and large tributaries, waters its whole extent. Its mountains, covered in many places with perpetual snow, are the loftiest, its valleys the most fruitful, in Spain. Andalusia, indeed, comprises four celebrated kingdoms; Granada, Seville, Cordova, and Jaen. They contain also great capitals founded by the conquering Moors, which were the seats of science and splendour, when the greater part of Europe was plunged in rudeness and barbarism.

2513. *Granada*, which is sometimes called Upper Andalusia, was the central seat of Moorish power and magnificence. Even amid the general decline of that power in Spain, Granada was still supported by the multitudes who resorted thither from the subdued provinces. Its fall, in 1492, was considered the most deadly blow which Islamism ever received; and in all the mosques prayers are put up every Friday for its restoration. Granada presents a wonderful combination of all that is most wild and sublime, with what is most soft and beautiful in natural scenery. North from the capital rises the Sierra Nevada, covered, as its name imports, with perpetual snow to a great depth. Mula Hascen, the most elevated peak, is stated by Mr. Jacob to be 12,762 feet above the sea; while the line of perpetual snow begins at about 10,000 feet. The Alpujarras, a lower range, are cultivated with considerable diligence, by descendants of the Moors, a remnant of whom found refuge here, amid the general proscription of their race and nation. The Vega or plain of Granada, watered by numerous streams descending from the high regions, displays nature in her utmost pomp and beauty.

2514. *The city of Granada* is in the heart of the Vega, beneath the loftiest heights of the Sierra Nevada. This city still displays ample monuments to attest the period when it was the great western capital of the Moslem world. Nothing can exceed the beauty of its approach. "The rich and populous country well supplied with trees, the clear rivulets descending from the mountains, and artificially contrived to intersect it in every part; the splendid city extending in a half-moon from the river, on the gradual ascent of a hill; the streets rising above each other; the profusion of turrets and gilded cupolas; the summit crowned with the Alhambra; the background composed of the majestic Sierra Nevada, with its summit covered with snow; complete a scene to which no description can do justice." Mr. Jacob, who thus describes the scene, considers it not too much to have travelled two hundred miles of bad road to see it. The interior, as in most Spanish and especially Mohammedan cities, does not correspond to the approach. The streets are narrow, the walls high and gloomy; many quarters are now deserted; and marks of decay and splendid poverty are every where visible. But the eye of the curious traveller is soon attracted towards the Alhambra (*fig. 272.*), the ancient palace and fortress of the kings of Granada. It is the

272

THE ALHAMBRA.

noblest specimen existing of Moorish architecture; and nothing perhaps in Europe, out of Italy and Greece, can come into competition with it. The site is fine, resembling that of Windsor, on a hill above the river. Its exterior structure, however, is the reverse of beautiful: a huge heap of ugly buildings huddled together, without the least seeming intention of forming one habitation; the walls only gravel and pebbles daubed over with plaster. On entering the threshold, however, the visitor seems transported into a fairy scene. He passes through a range of apartments; the baths, the Court of the Lions; the

- Hall of the Abencerrages (*fig. 273.*); the Golden Saloon, or Hall of the Ambassadors; the Gate of the Sanctuary of the Koran (*fig. 274.*); the Tower of the Two Sisters; with others, in which the various resources of Oriental pomp are displayed, along with all that can refresh the eye or the sense in a sultry climate. The courts are all paved with marble, and sur-

rounded with marble pillars, in a pure and beautiful taste; and the walls and pavement are

273

HALL OF THE ABENCERRAGES.

274

GATE OF THE SANCTUARY OF THE KORAN.

profusely ornamented with gilded arabesque and mosaic (*fig. 275.*), the colours of which, by an art which seems to have been lost with the Moors, are as brilliant as when they were first laid on, five hundred years ago. Water is made to spout into the air, or, in smooth sheets

275

MOSAIC PAVEMENT.

bordered with flowers, refreshes the interior of the apartments. After the expulsion of the Moors, Charles V. built on part of its site a new palace, the external architecture of which was much superior; but it was never finished. The Generalife is another Moorish palace, in a more elevated and finer situation; but its interior splendour, though great, is quite eclipsed by that of its neighbour. The cathedral, though it must yield to these Moorish structures, is yet of considerable extent and beauty. Granada is the seat of one of the two high courts of chancery, and of other tribunals of high jurisdiction. It retains a certain proportion of its former immense silk manufactures, with some of woollen and leather; and a considerable number of persons are employed in extracting the nitre with which the neighbouring soil is copiously impregnated.

2515. *Malaga* has in modern times attained a greater importance, and is reckoned the third port in the kingdom, ranking next to those of Cadiz and Barcelona. The chief

foundation of its trade is the fine wine called Malaga or *mountain*, produced in the numerous hills behind it. It is raised at very great expense, and only upon the declivities which have an exposure to the sun. The country produces also very fine raisins and other fruits; and anchovies, caught and cured on the coast, have been sold to the annual extent of 20,000 quintals. Malaga is the only great Spanish port of which the exports have always exceeded the imports. Mr. Townshend estimated their annual amount at 375,000*l.*; Laborde at 560,000*l.* Malaga has a very secure though not extensive harbour, formed by artificial moles. It lies in a deep bay on a little plain overhung by lofty and craggy cliffs, which at a distance appear quite naked, but on approaching, every crevice is found to be filled with vines. This situation renders the heat very severe, and has aided in exposing the inhabitants to the destructive ravages of pestilential fever. The streets are close, narrow, and dirty; but the cathedral is a very noble pile, and contains paintings by great Spanish masters.

2516. *Other very considerable towns occur in Granada.* Five leagues to the east of Malaga is Velez-Malaga, most delightfully situated in a plain diversified by numerous gentle hills, clothed to the summit with vines, while the plains below wave with luxuriant harvests of grain. Farther east are the small ports of Motril and Almeria; the latter ancient, and celebrated in the history of the Moors, under whom it was highly prosperous and flourishing. Near it is the rock of Filabres, 2000 feet high, composed of a single block of white marble; and beyond it stretches into the sea the bold and huge promontory of Cabo de Gata. Guadix, Baza, and Purchena, are considerable interior towns, in the eastern part of this province, seated in valleys enclosed by the numerous ranges of hills which intersect it. Santa Fé, two leagues west of Granada, is remarkably exposed to earthquakes, which have split its cathedral in two, and laid open the cells of one of the convents; yet the citizens still inhabit and keep it in repair. Alhama is strikingly situated amid a circuit of precipitous rocks, through which dashes a rapid stream. It is frequented for the salubrity of its air, and for its medicinal springs and baths. Antequera is very ancient; filled with Roman and Moorish monuments, and still large; the adjacent country is very fertile, and distinguished for the variety both of its vegetable and mineral productions. Ronda,

RONDA.

(fig. 276.) capital of a wide mountain district, is singularly situated on a rock with perpendicular cliffs and broken crags, through a deep fissure in which the river flows, and surrounds the city on three sides. It is crossed by a stupendous bridge 110 feet in diameter, and 280 feet in height. Stairs of 350 steps lead down to the river, and gardens have been formed on some level projecting points of the precipice. The mountaineers of Ronda are an honest, active, hardy race; and so healthy as to make it a proverb, that "at Ronda a man is a boy at eighty." The vicinity of Gibraltar gives them great opportunities for smuggling, which they carry on in large bands, and in open resistance to government, without, however, incurring any imputation on their general loyalty.

2517. *The kingdom of Seville, east of Granada, is a still finer region, and perhaps superior to any other in the Peninsula.* Its plains are the most productive in wine, oil, and fruits; the noble river Guadalquivir conveys its products to the sea; and Seville and Cadiz are, in some respects, superior to all other Spanish cities.

2518. *Seville (fig. 277.) is situated in the midst of a fertile and delightful plain, and*

SEVILLA.

near the mouth of the Guadalquivir, which formerly admitted vessels of large size: it was a great city from the earliest period. By the Romans it was celebrated under the appellation of Hispalis: its foundation was ascribed to Hercules; and, with the neighbouring colony of Italica, it formed the capital of Bætica. Under the Moors it became an independent kingdom; and if it be true that, on its capture by Ferdinand the Catholic, 400,000 Moors marched

out at one of its gates, it must indeed have been an immense city. Notwithstanding the depopulation thus occasioned by bigotry and treachery, it soon became more splendid than ever, in consequence of becoming the emporium of the wealth which flowed in from the western hemisphere. Its manufacturing industry was then also very flourishing. By a return made

to government in 1601, Seville was said to contain 16,000 silk looms, giving employment to 130,000 workmen. It frequently received an increase of splendour by becoming a royal residence. Since the above period, Seville has not only declined with the gradual decline of Spain, but has suffered by the filling up of the channel of the Guadalquivir, which has rendered it navigable only for small ships, and has transferred to Cadiz the commerce of America. Seville is now a solemn, inert, gloomy city. Like other Spanish places, particularly those of Moorish origin, its streets are narrow, winding, and dirty; but it contains some splendid public edifices. Foremost stands the cathedral, the largest ecclesiastical structure in the Peninsula, 420 feet long within, and 373 broad; but the most striking feature is its tower, originally erected by the learned Geber or Guever, and used as an observatory, but raised by the Christians to the height of 350 feet. Many of the convents also are very splendid, and previous to the late invasion by the French contained numerous works of the greatest Spanish artists, of whom Seville was the chief nurse. There was, above all, a splendid collection of the works of Murillo, the prince of these artists, and a native of Seville. Of these treasures the city has been in a great measure despoiled by the ravages of the invader; Marshal Soult, in particular, has in his collection numerous master-pieces of Murillo, by which the convents of Seville were formerly adorned. Seville has still 2500 silk looms; and government maintains a cannon foundery and a tobacco manufactory. The Exchange and the Marine Academy are also handsome edifices.

2519. *Cadiz* (*fig. 278.*) is, in an equal degree with Seville, the boast of Spain. In the

CADIZ.

commercial annals of the world no city is of higher antiquity. Tartessus, occupying a site in its vicinity, was one of the earliest and most flourishing Phœnician colonies. Afterwards Gadeira, or Gades, was recognised by the Greeks and Romans as one of the chief European emporia. In modern times, when commerce did not form part of the European system,

Cadiz declined into a secondary rank; and the intercourse with America was at first nearly monopolised by Seville. The circumstances which transferred it from that city to Cadiz took place early in the last century, when the latter rose to be the chief theatre of Spanish commerce. It enjoyed for some time the entire monopoly of the American trade; and even when, in 1778, it was thrown open to the whole kingdom, it had taken such deep root in Cadiz as to frustrate all competition. In 1784, when the entire imports from America were 12,630,000*l.*, that city, for its share, had 11,280,000*l.*; and of the whole exports, amounting to 4,300,000*l.*, it had 3,600,000*l.* Notwithstanding severe shocks, in consequence of political revolutions, and the war with England, it always revived, and derived a temporary greatness from becoming the capital of the constitutional government. It received, however, its mortal blow by the separation of the colonies. The merchants, deprived thus of almost their only employment, have been reduced to the funds already accumulated, and have in a great measure retired from the confined situation of Cadiz to the pleasant sites and villages which are scattered round the bay. The city is situated on a small neck of land, at the point of the long Isle of Leon. It does not boast any remarkable structures, but the whole is elegantly built in regular squares, and streets with a square court in the centre and an awning over it.

2520. *Gibraltar* (*fig. 279.*), though no longer Spanish, forms also a striking and important

GIBRALTAR.

feature in this province. This rock is celebrated from the earliest antiquity as one of the two "Pillars of Hercules," which guarded the entrance into the Mediterranean; though Mount Calpe, on the opposite side, is considerably loftier. In 1704, Sir George Rooke and Sir Cloudesley Shovel carried this fortress by a *coup de main*; since which time Spain has vainly attempted to regain

possession of it. Her grand effort was towards the close of the American war, when the fleets of France and Spain rode masters of the sea. A combined attack was made on the 13th of September, 1782, by the two powers, with fifty sail of the line, 30,000 troops, and ten mighty floating batteries, which were expected to demolish all opposed to them. They kept up a tremendous fire from ten in the morning till mid-

night, at which time smoke and fire were seen rising from the batteries, which before next morning were reduced to ashes, with a dreadful destruction of the assailants. No subsequent attempt has been made; nature, in fact, has rendered Gibraltar almost impregnable. The rock is precipitous on all sides, and is connected with the continent only by a narrow neck of marshy ground. The western front alone towards the sea is in any degree accessible; and this is defended by batteries cut in the solid rock, and by other works so extensive and so well planned as to bid defiance to any future effort. Gibraltar has one handsome street, the houses of which are built in the English style, with trees and flowers skilfully planted in scanty fragments of soil. The rest of the town is close, crowded, and dirty, inhabited by about 20,000 people, chiefly Moors and Jews, the latter of whom have sought refuge here in great numbers from Spanish bigotry, and have four synagogues. The expense of maintaining Gibraltar is considerable: but it forms an important naval station, a depôt for the commerce of the Mediterranean, and a channel for introducing into Spain great quantities of goods, declared contraband by the jealous policy of that country.

2521. Among other places of some importance is *Tarifa*, the most southern part of Spain, and even of Europe, and the probable place of the landing of *Tarik*, with the Saracen army destined for the conquest of that country. Seated on an almost insulated rock, it is still a fortress of some strength. *Algesiras*, on the opposite side of the bay, has grown up as a small rival to Gibraltar; its population consists chiefly of smugglers and adventurers. In the interior is the flourishing and populous town of *Xeres*, situated in a wide region of vineyards, producing the wine called *Sherry*, the consumption of which is so general in this country. Mr. Jacob supposes the entire produce to be 40,000 pipes, of which 15,000 are exported, one half to Britain. *Ecija*, a large town, was famous as a scene of contest between the Christians and Saracens, and afterwards as the head quarters of a most formidable band of robbers; but its walls are now in ruin. *Lebrija* and *Carmona* are ancient towns, containing Roman monuments of considerable grandeur. The districts to the north and west of the *Guadalquivir* are mountainous and rugged; though *Huelva* and *Moguer*, at the mouth of the *Tinto*, and *Ayamonte*, at the mouth of the *Guadiana*, derive some importance from their situation, and carry on a little fishery.

2522. *Cordova* (*fig. 280.*), on the upper part of the course of the *Guadalquivir*, is another

280

kingdom of Andalusia, deriving its chief interest from the celebrated capital of the same name. *Corduba*, founded by the Romans, was not only a provincial capital, but the seat of an university, which could boast the great names of *Seneca* and *Lucan*. It

displayed, however, a far higher pomp, when, after the Saracen conquest, it became the first capital of the Mohammedan empire in Spain. Under *Abdelrahman* and *Almansor*, it is represented as containing 1600 mosques, and nearly 1,000,000 people. Ad-

281

INTERIOR OF MOSQUE AT CORDOVA.

mitting a certain exaggeration, its past greatness is clearly attested by the vast and now almost empty circuit enclosed by its walls, in a great measure filled with palm trees and gardens, and by the astonishing remains of its mosque. This vast edifice presents nothing very striking in its exterior, which is in a great measure hid by the surrounding streets. But when the stranger enters any one of its nineteen gates, he is astonished and bewildered by the endless labyrinth of columns which stretch before him in every direction (*fig. 281.*). These columns have almost defied the attempts to number them; by one writer they have been estimated at 1400, but are generally stated as exceeding 400, dividing the mosque into nineteen aisles, and producing a perpetual and surprising change of scene to the visitor. The edifice, however, though it astonishes by its immensity, does not equal in elegance those erected during that more refined age when *Granada* became the capital. The Christians have converted it into a church, and erected in the centre a choir of great beauty, but quite out of harmony with the Saracenic part of the structure. *Cordova*, though its days of splendour are long departed, still enjoys delightful environs, producing a breed of horses the finest in Spain,

of which a splendid stud was lately kept by the government. There is also some rem-

nant of its once extensive manufactures, particularly of that fine species of leather called from it Cordovan. The population is supposed somewhat to exceed 30,000.

2523. *Jaen* ranks as a fourth kingdom, though it cannot enter into any rivalry with those already described. Its capital, of the same name, however, though little known, from its detached situation, is still a large city, the see of a bishop. Andujar is a considerable place, with a very ancient castle, at the entrance of the defiles of the Sierra Morena; and to the north of it is Baylen, where the Spaniards gained that signal victory which caused the surrender of Dupont and his army. In the upper part of this tract are the settlements of La Carolina, where an expanse of rude mountain waste has, by German and other colonists, been converted into a productive territory.

2524. *The Balearic Islands*, Majorca, Minorca, and Iviça, with the minor ones of Cabrera and Formentera, form an appendage to Spain of some importance and celebrity. The Balearian slingers are celebrated in the military annals of antiquity; but the islands in general followed the political fate of Spain. Majorca, the largest, about forty miles in length, and thirty in breadth, possesses very considerable natural advantages. Several mountain chains, varying from 1500 to 4500 feet high, penetrate its centre, and defend it both from the excess of the heat and the violent action of the sea breezes. Its summits are somewhat arid, but the intervening valleys are thickly clothed with olive trees; and corn and the vine grow luxuriantly, though with imperfect culture, on the plains below. Oranges and citrons flourish so abundantly in the northern district, that 20,000 mule-loads of them are exported to France and Catalonia. M. Cambassedes values the entire produce of the isle, in 1820, at 53,000,000 reals, about 660,000*l.* Of this, about 34,000,000 are in grain and pulse, 5,000,000 in oil, and 2,500,000 in wine, 1,500,000 in fruits, 3,000,000 in hops, and 2,000,000 in sheep. Palma, the capital of Majorca, is a considerable town, slightly fortified, inhabited chiefly by the nobles, who possess the greater part of the isle, and have rarely sufficient activity or curiosity to visit their estates. In no Spanish city are indolence and superstition more prevalent. There are thirty convents, some of which enjoy a revenue of more than 2000*l.* a year. Processions and religious festivals, celebrated often with great tumult, form the chief amusements. In these it is customary to deck up figures of Judas, with tablets containing the enumeration of his crimes, among which that of being "chief of the liberals" was lately included!

2525. *Minorca* is a much smaller island, more barren, covered with bare and rocky mountains, and destitute of any trees at all lofty, the growth being prevented by the violent winds from the sea. But it is distinguished for one of the finest harbours in Europe, Port Mahon, which being strongly fortified, has been a subject of eager contest to the maritime nations. Having been taken by England in the Succession War, it was recovered by the French in 1756, notwithstanding Byng's attempt to relieve it. After several other vicissitudes, it remained with Spain. The harbour is extensive, possesses deep water, and is sheltered by hills on each side from every wind. The town has nothing of a Spanish aspect; the streets being broad, the houses small but neat, the people a stirring and active race, who scarcely allow themselves to be called Spaniards. During the late French war, being protected by the English navy, they made considerable wealth by privateering. Cividarella, though of smaller extent, is the nominal capital, and the residence of the nobility. Iviça, or Iviza, is a small isle, of rugged surface, which forms one immense mountain, shooting up into a variety of summits. The island is thus refreshed by cool breezes and numerous streams, and yields readily all the productions of this climate, particularly figs. In the quarter called Las Salinas, salt is evaporated by the heat of the sun, and exported to the extent of 15,000 tons.

CHAP. VII.

PORTUGAL.

2526. *Portugal* has by political causes alone been separated from Spain. There is no physical peculiarity by which the two kingdoms are distinguished. On the contrary, all the grand natural features of Spain are prolonged into Portugal, and become Portuguese.

SECT. I. *General Outline and Aspect.*

2527. *The boundaries* of Portugal are the Atlantic Ocean on the west throughout its whole extent, and also on the south; on the north the Spanish kingdom of Galicia; and on the east those of Estremadura and Leon. The greatest dimension is from north to south, or from 37° 3' to 42° 12' north latitude, and from 6° 15' to 8° 55' west longitude. Its surface has been reckoned at 40,875 square leagues.

2528. *The mountains of Portugal* may be considered as prolongations of those of Spain,

chiefly of the chains of Guadarrama and Toledo, and those in the north of Galicia. Those ranges, seldom rising to the first magnitude, cover almost the whole country, leaving between them many picturesque and fertile valleys. There are only two extensive plains, one on the south of the Tagus, and the other between the Mondego and the Douro.

2529. *The rivers of Portugal* consist chiefly of the spacious terminations of the greatest streams of Spain, in their progress to the ocean. The Douro forms the great maritime emporium of Oporto, and the Tagus that of Lisbon. The Guadiana, also, in its lower course, flows along the eastern frontier of Portugal. The Minho, a much smaller stream, comes down from Galicia; and the Mondego, alone, is entirely Portuguese, flowing nearly across the breadth of the kingdom.

SECT. II. *Natural Geography.*

SUBSECT. 1. *Geology.*

2530. *This kingdom has the same general geognostical structure and composition as Spain.* The mountainous parts of the country are generally of gneiss, mica slate, and other Neptunian primitive strata, occasionally intermingled with Plutonian rocks of granite and porphyry. Secondary formations of limestone occur in the Sierra d'Estrella, and in the vicinity of Cape St. Vincent, and all around Lisbon and at Cape St. Vincent the strata are of rocks of the tertiary class, more or less intermingled with trap rocks.

2531. *Mines.* It appears that the Carthaginians wrought tin mines in this part of the Peninsula. It is asserted that there were formerly mines of tinstone in the granitic mountains of the neighbourhood of Viseu, in the province of Beira, at the place called Burraco de Stanho. Lead ores were worked in the last century, not far from Mogadouro, on the banks of the Sabour, in the province of Tras los Montes, and near Longroiva, on the banks of the Rio Prisco. Near Mogadouro, mines of graphite or plumbago occur. Iron mines also occur in the same country, near Felguiera and Torre de Moncorvo. They supply the iron forge of Chapacunha. Two very old establishments of the same kind occur in Portuguese Estremadura, one in the district of Thomar, the other in that of Figuero dos Vinhos. They are supplied by mines of red oxide of iron, situated in the frontier of that province and of the province of Beira. There is a deposit of cinnabar at Couna. The mountains of the neighbourhood of Oporto every where present indications of copper and of other ores. In Portugal, as in Spain, the sands of rivers were washed for the gold they contain; and it is said in this way large quantities of the precious metal were collected. At present there is but one gold mine in Portugal, at a place called Adissa, in the district of St. Ubes. Its annual produce is trifling: in the year 1815 it was 41 lbs. of pure gold; 1816, 18 lbs.; 1817, 11 lbs.; 1818, 12 lbs.; 1819, 13 lbs.; 1820, 12 lbs.; and in 1821, 18 lbs. Beds of coal occur at Vialonga, to the N. N. E. of Oporto; and there is a mine of coal at Cabo de Buarcos in the province of Beira.

SUBSECT. 2. *Botany.*

2532. *The Botany of Portugal* is included under that of Spain.

SUBSECT. 3. *Zoology.*

2533. *The zoology* cannot be very different from that of Spain; but no documents have appeared to illustrate either the one or the other. The horses are rather small, and altogether inferior; but the mules are fine, and nearly equal to those of Spain. Improvement, however, is neglected: nor have the indolent Portuguese profited by crossing their sheep from the merinos of Spain. A long-legged race of swine is common to both kingdoms, and furnishes excellent hams.

SECT. III. *Historical Geography.*

2534. *The Carthaginians and Romans*, who occupied the Peninsula, did not recognise Portugal as a distinct country. Their Lusitania included a part of Spain, and did not comprise the whole of Portugal: Merida, in Estremadura, was its capital. Portugal, like Spain, submitted successively to the formidable irruptions of the Goths and of the Moors.

2535. *The existence of Portugal as a distinct kingdom* dates from the commencement of the twelfth century. At that time, Henry, duke of Burgundy, having married the daughter of the duke of Castile, obtained as her dowry the northern part of Portugal, which had been rescued from the Moors. The capital, at that time, was Porto, or Oporto, whence the modern name of the kingdom appears to be derived. His successors gained a series of conquests, and obtained possession of Lisbon and the southern provinces, carrying their conquests to the frontier of Seville.

2536. *The fifteenth century*, and the reigns of John and Emanuel, formed the true era of the greatness of Portugal, when it outshone all the other kingdoms of Europe. Confined on the land side within narrow limits, it opened for itself a vast career of maritime discovery and conquest. Spain, indeed, shared this pursuit; but her first acquisitions were made by private individuals, partly foreign, with only faint assistance from the government; while

the Portuguese expeditions were planned, fitted out, and all the resources for them supplied by the government. Their flag, at one time, floated victorious over all the eastern seas; while in the west, by the possession of Brazil, they came into some competition with Spain.

2537. *A disastrous eclipse of the Portuguese monarchy took place in the sixteenth century*, in consequence of the rash and romantic expedition undertaken by king Sebastian into Morocco, where he himself and the flower of his troops were cut off. Hereupon Philip II. of Spain, a powerful and ambitious prince, raised a claim to the succession, which the superiority of his arms enabled him to secure. Portugal, with all her eastern and western possessions, then became an appanage to the crown of Spain. The connection was every way unfortunate. Not only did she lose her political and civil liberty, but many of her finest foreign possessions were wrested from her by the Dutch, the spirited and active enemies of Philip.

2538. *The restoration of the monarchy*, in 1640, was still more sudden than its fall. The deep-rooted indignation of the people was combined into extensive conspiracy, which, having been concealed to the last moment, burst forth at once: the Spaniards were driven out, and the duke of Braganza raised to the throne, under the title of John IV. Yet Portugal did not thus achieve any revival of her ancient glory. The new monarch soon re-established absolute power: a sluggish and indolent character pervaded all the departments of government; its foreign possessions were lost or neglected; and Portugal continued a stranger to all the improvements and energies which raised Britain and France to the first place in the system of Europe. Yet, during this period, the elevation of our enemies, the Bourbons, to the Spanish throne, led to a very intimate alliance between this country and Portugal, the natural foe of Spain. It was cemented, in 1803, by a commercial treaty, in which Portugal secured an exclusive market for her wines, while Britain obtained a market for her woollens, and an arrangement by which the gold of Brazil might find its way into her ports.

2539. *The recent convulsions of the Peninsula have been very amply shared by Portugal*. Regardless of the neutrality which she had strictly maintained, Bonaparte, by a most unprovoked aggression, sent Junot, in 1807, to take possession of Lisbon. The king did not attempt a vain resistance, but sailed for Brazil, and established his court at Rio de Janeiro. The British arms, and the glorious achievements of Wellington, drove the French out of this part of the Peninsula, and finally out of the whole. Afterwards Portugal imitated the example of Spain in compelling her monarch to grant a representative constitution; but again, by a counter-revolution, she re-established an absolute monarchy. More recently, on the death of the late king, Don Pedro proclaimed the separation of Brazil from Portugal, reserving the former to himself, but granting to the latter a charter, the observance of which was made the condition of holding the throne. This charter has been rendered nugatory by the successful usurpation of Miguel, brother to Pedro, who, however, having occupied Oporto, has endeavoured to support the claims of his daughter, Maria de Gloria.

SECT. IV. *Political Geography.*

2540. *Portugal, after the downfall of the feudal system*, and especially after her subjection to Philip II. became one of the most absolute of European governments. The will of the sovereign, and a constant system of intrigue, directed all its operations. The Marquis of Pombal and one or two more enlightened men found their way into the ministry; but, in general, measures were as ill conducted as possible, and corruption prevailed in every department of the state. The course of justice was equally polluted; and, no adequate salaries being allowed to the judges, they were under an almost irresistible temptation to accept bribes. The pride of the nobles was nearly as great as in Spain, without being accompanied by the same lofty sentiments. They are divided into two branches, the *titulados* and the *hidalgos*, and have held the peasantry in a subjection little short of slavery.

2541. *The army of Portugal, prior to the revolution*, though composed nominally of 30,000 men, was in a most inefficient state, not through want of physical courage or discipline in the men, but from the incapacity of the officers, and the general defects of the military system. When the French, however, had been driven out of Portugal, an army of 40,000 men was levied, and disciplined by British officers, under the superintendence of Lord Beresford; and thus prepared, the Portuguese acted, during the eventful war which followed, in a manner that would not have disgraced any troops in Europe. The army is still maintained; and though the new government will not brook British command, yet, under its influence, Portuguese officers of merit have been formed.

2542. *The navy*, which was never considerable, was carried out with the royal family to Brazil, and has never been restored.

SECT. V. *Productive Industry.*

2543. *The industry and commerce of Portugal*, which presented so brilliant an aspect during her era of prosperity, have sunk lower than those of almost any other European nation.

2544. *Agriculture* did not, until very lately, experience any of the improvements which have become general in the rest of Europe. The plough is composed of three pieces of wood awkwardly put together, and imperfectly aided by the clumsy machinery of wheels. Though generally very fertile, this country did not produce a third of the grain necessary for the supply of its inhabitants. Of late some improvement has taken place, especially by the introduction of potatoes; and the dependence upon foreign supply has been considerably diminished. The chief object of attention is the vine, which, with the olive and other fruit trees, is cultivated with the utmost diligence in the valleys and on the sides of the hills, in the elevated province of Entre Douro e Minho. Here is produced abundantly the port wine, which forms the main basis of Portuguese trade, and finds so copious a market in Britain. The entire produce is estimated at 80,000 pipes. Of white wine Portugal produces about 60,000 pipes; but this is of inferior quality, and chiefly consumed at home. Sheep are bred on the hills, to a pretty large extent; but not so abundantly as in Spain, neither is their wool so fine.

2545. *The manufactures* of Portugal scarcely deserve to be named. Little is known beyond the working of their wool for domestic use by each family or neighbourhood; all their finer fabrics are imported. According to a late observant traveller, ignorance, or at least an imperfect knowledge of the commonest arts, is conspicuous among the Portuguese. Their carpenters are the most awkward and clumsy artisans that can be imagined, spoiling every thing they attempt; the wood-work even of good houses being finished in a manner that would scarcely have been tolerated in the rudest ages. Their carriages of all kinds, their agricultural implements, locks, keys, &c., are ludicrously bad. Working in gold and silver plate forms almost the only exception; cambrics also are well made in some places; and a few other local objects might be enumerated.

2546. *Of mines and fisheries*, the former is not at all cultivated, though great materials for it are said to exist; but in the absence of trial this may be only conjecture. Fish of the finest kinds, particularly tunny and sardinias, are caught in considerable quantity for immediate consumption; but the salt which the kingdom so abundantly produces is not used for preserving them; and a large import of salted fish is still necessary to meet the wants of a population so rigidly catholic.

2547. *The commerce*, which formed the greatness of Portugal, when her ports interchanged the products of the East and the West, is now a mere shadow. The loss of her Indian possessions, and the separation of Brazil, have reduced her to the common routine of export and import. The staple of the former is port wine, for which the market of England was secured first by favouring duties, and now seemingly by an established predilection. The wine is raised almost solely for the English market, and all of the best quality is bought up by English merchants residing at Oporto.

2548. *Another staple export* of Portugal is salt, evaporated by the heat of the sun in the bay of St. Ubes, or Setubal, which seems as if expressly formed for that purpose. It is carried off chiefly by the English, to be employed in curing the fish destined for the Portuguese market: the annual amount is estimated at 100,000 tons, value 300,000*l.* sterling. There is also a considerable surplus of wool, of which 1,000,000 lbs. weight have been imported into England in one year; but as it is not so fine as that of Spain, the duty imposed by the British landholders has greatly checked the importation. In return, Portugal takes grain, salt fish, and a variety of manufactures, chiefly from Britain; but as her imports cannot much exceed the exports, she cannot afford a very copious market.

2549. *The internal communications* of Portugal consist of the several noble rivers which traverse her territory, and which are navigable throughout. The intercourse by land is rendered very difficult by chains of mountains extending in the same direction. Nothing has been attempted on any important scale, either to improve these advantages, or to amend the defects; so that travelling is worse in Portugal than in any other European country.

SECT. VI. *Civil and Social State.*

2550. *The population* of Portugal, according to the last census, which was taken in 1798, amounted to 3,683,000; calculating at the somewhat high estimate of five to a family. Upon a surface of 40,000 square miles, this gives a density of about ninety-two to the square mile, which is remarkable, as exceeding that of Spain nearly in the proportion of three to two. The exemption from the *mesta*, and the high cultivation of the province of Entre Douro e Minho, appear to be the redeeming circumstances in her case.

2551. *No nation, as to character, owes less to the opinion of the world, than the Portuguese.* They are described as indolent, dissembling, cowardly, destitute of public spirit, and at the same time fierce and deeply revengeful. In Spain it is said, strip a Spaniard of his virtues, and he becomes a good Portuguese. From a late minute inspection, however, the peasantry (*fig.* 282.) have been pronounced to be a fine people; and, on repeated occasions, during the late war, they displayed energies not unworthy of their ancestors, in an age when their glory resounded throughout both hemispheres. Almost all, however, that floats

on the surface is base and degenerate.

282

PORTUGUESE PEASANTRY.

(fig. 283.). The number of two archbishops and thirteen bishops is not so disproportionate.

283

PRIAR AND NUN.

There cannot be a doubt that this may be greatly ascribed to priestcraft, to the stupifying influence of a sluggish and tyrannical government, and to the general corruption which has pervaded all the branches of administration.

2552. *The established and exclusive religion is the catholic, in its extreme and most degrading excess; and the body of the people are almost entirely under the thralldom of the priesthood. The burning of Jews continued till within the last half century. The physiognomy of a large proportion of the people shows their descent from this hated race, whose tenets many, it is probable, still cherish in secret. There are, in Portugal, about 550 religious houses, of which 150 are nunneries.*

2553. *The literature of Portugal, during the period of its glory, was by no means contemptible. The genius and fate of Camoens spread his name throughout Europe, and entitled him to rank among the few modern epic poets. By the students of Portuguese literature, however, Saa Miranda and Antonio Ferreyra are reckoned scarcely second to him; and Rodriguez Lobo held the nation long enchanted by the sweetness of his pastorals. At the same time Di Barros, Castanheda, and Faria y Sousa, recorded, in magnificent though somewhat inflated historical narrative, the mighty exploits of their countrymen in*

the African and Indian seas. The subjection to Spain gradually divested Portuguese literature of its manly and energetic character. The muse of history was silent; poetry assumed the form only of the sonnet, and Gongora infected it wholly with a strain of false and meretricious ornament. The house of Braganza for some time did little for knowledge; but in the beginning of the last century, the Conde de Ericeyra introduced the French literature, and founded a royal academy. In the course of the century, Barros Pereyra, Antonio da Lima, Manuel da Costa, a Brazilian, Correa Garcas, and Paulino Cabral, a bishop, made not unsuccessful efforts to revive the ancient Portuguese poetry, and to introduce that of Italy. Portugal has two universities. That of Coimbra, founded at Lisbon in 1290, was transferred to Coimbra in 1308. It enjoys some celebrity, is divided into eighteen colleges, and is still attended by several hundred students; but the course of study is of that obsolete description which prevailed during the middle ages. A smaller university was founded at Evora in 1578.

2554. *For the minor particulars of amusement, dress, food, &c., reference may be made to Spain, as Portugal has no peculiarities that are more than provincial.*

SECT. VII. Local Geography.

2555. *Portugal is divided into the following six provinces, several of which, like those of Spain, in reference to events in their past history, are sometimes called kingdoms: —*

	Square Leagues.	Extent in English Acres.	Population.
Estremadura - - - -	823	5,450,880	826,860
Alemtejo - - - -	883	5,848,320	380,480
Algarve - - - -	232	1,536,000	127,613
Beira - - - -	753	4,994,600	1,121,595
Entre Douro e Minho - -	291	1,927,040	907,965
Tras os Montes - - -	455	3,007,760	318,665

2556. *Estremadura occupies a great extent of coast, both to the north and south of the Tagus, without ever penetrating very deep into the interior. It presents a rocky, varied, and picturesque surface. It is chiefly important, however, as containing Lisbon, the capital.*

2557. *Lisbon (fig. 284.) is situated near the mouth of the Tagus, which may here be almost considered an arm of the sea, since not only the tide flows up, but the water is salt, and the swell often tempestuous. The approach to it presents a more magnificent spectacle than that of perhaps any other city of Europe. The city rises direct from the water.*

crowning the sides and summits of several hills; which, according to the Portuguese, are seven in number, like those of Rome. The palaces, convents, and churches, which crown

284

LISBON.

this amphitheatre of buildings; the dazzling whiteness of the houses; the light appearance of the windows and balconies; the tasteful arrangement of plants, shrubs, and flowers on their roofs and terraces; the golden orange groves which adorn the suburbs, and the stately specimens of Indian or American botany which are scattered through the scene, produce an effect that cannot

be described. The noble harbour, also, crowded with vessels; the numerous pilot and fishing-boats, with their large, handsome lateen sails, ascending or descending the river; and, nearer the shore, hundreds of small neat boats, with white or painted awnings, finely vary the scene. The moment, however, that the stranger lands, and enters the place, he finds that he has been imposed upon by a brilliant illusion; and the gay and glittering city is found to resemble a painted sepulchre. The streets are narrow and ill paved; the houses gloomy, with here and there a latticed window; filth and nuisances assault him at every turn. Lisbon does, indeed, appear to be the dirtiest and most noisome city on the face of the earth. In passing through the streets, a stranger encounters at every turn the most disgusting effluvia. Every species of vermin destined to punish indolence and slovenliness, the mosquito, the scolopendra, and a species of red ant, multiply to an extraordinary degree. Nor is Lisbon found, on inspection, to exhibit that architectural beauty which it promises on a distant view. It might have been expected, among forty churches and seventy-five convents, built by a superstitious people, that there would have been some signal display of this kind; but this is not found even in the cathedral. The defect seems partly owing to the mean taste of the Marquis of Pombal, who ordered them to be all built on a line with the street, to preserve a dull uniformity. Two handsome squares, however, have been formed, the Commercial and the Roscio, which are connected by well-built streets; but the absence of trees, or even shrubs, and the blinding sand that drifts through them, combine to produce a disagreeable effect. Lisbon derives an awful interest from the ruins still left of the great earthquake of 1755, the most dreadful catastrophe which ever befell a modern European city. Six thousand houses were thrown down, 30,000 inhabitants killed; and a conflagration kindled which spread a still wider destruction. The ruins are the more dismal, as they portend similar disasters, which the earth, still heaving from time to time, perpetually threatens. Meantime Lisbon displays one very grand feature; the aqueduct, to the construction of which, though it conveys the water only half a mile, peculiar obstacles were presented. It is carried in one place through a tunnel, and in another over a defile 230 feet deep, by arches, which are said to be the highest in the world. The width of the centre arch is 107 feet. It was built in 1738, by Manuel de Maya; and is of such solidity that it withstood the shock of the great earthquake, which only caused the keystone to sink a few inches.

2558. *The vicinity of Lisbon* presents some beautiful sites and palaces. Cintra is the most striking, consisting of an immense mountain, partly covered with scanty herbage, partly with broken, huge, and varied piles of rock, elsewhere presenting thick groves of cork, elm, oak, hazel, and other trees. It includes many lovely and fantastic spots; but the view from it is naked and dreary. The town, at the bottom, with its old palace, has nothing remarkable; but the sides are covered with delightful villas, one of which is notorious for the signature of the unhappy convention of Cintra. Mafra is a royal convent built by John V., in emulation of the Escorial; but though a stupendous pile, 700 feet square, and containing numberless suites of ill-furnished apartments, it ranks far below its model. Only five miles below Lisbon, of which it is considered a suburb, is Belem, the site of a palace and a very magnificent monastery, founded by Emanuel, and in which many of the royal family have been interred.

2559. *There are several other towns of some note in Portuguese Estremadura.* St. Ubes or Setubal lies sixteen miles from Lisbon, on the coast south of the Tagus, on a long interior bay, the waters of which, evaporated by the heat of the sun, leave the excellent bay-salt, one of the national staples. The town is considerable, having been well rebuilt since the earthquake of 1755, when it was almost totally overthrown. The mountain of Ursabida, here extending into the sea, forms a bold and striking promontory, covered with trees and various vegetation. Ascending the Tagus, we come to Santarem, a considerable and ancient town, the Præsidium Julium of the Romans. It has an academy of history, established in 1747. Here the great French army, under Massena, remained long posted, unable to penetrate to Lisbon. Abrantes, higher up, is an important military position, situated on a height whence it commands the passage of the Tagus. Leiria, to the north,

is an ancient town, in a most productive territory, and where a great annual fair is held for the supply of the peasantry of the neighbouring country round. At Batalha is a church (fig. 285), and monastery which, united, form the finest structures in all Portugal. It is 541 feet by 416, and is considered by Mr. Murphy to be one of the noblest existing specimens of the Norman Gothic. It is constructed entirely of marble, and the front appeared to him almost unrivalled in chaste and delicate ornament. Among the different parts, the mausoleum erected in honour of King John, is pre-eminently beautiful (fig. 286). Vimiero

CHURCH OF BATALHA.

MAUSOLEUM OF KING JOHN.

is only a village, but celebrated for the signal victory gained by the British over the army of Junot. Three miles distant is Torres Vedras, a tolerable old town, but chiefly noted as the centre of the grand fortified lines formed by Wellington in 1810, which so completely baffled all the manœuvres by which the French had hoped to reconquer Portugal.

2560. *Alemtejo* is an extensive province, comprising the greater part of Portugal south of the Tagus. The interior presents an extensive plain; but the frontier towards Spain is finely diversified with hills, wooded mountains, and deep valleys extremely well watered, and very fertile. It contains some large towns. Evora, the third in the kingdom, is situated on an eminence in a fine country, and is of great antiquity. Its origin has even been dated seven centuries before the Christian era. It is more clearly ascertained that the Romans made it a municipal town, and adorned it with some of their finest structures. There is a noble aqueduct, of which the piers are nine feet broad, and supported by buttresses; also a Temple of Diana built by Sertorius, in which great elegance is displayed. Elvas, on the Spanish frontier, immediately facing Badajos, is the strongest fortress in Portugal, and designed as the barrier of the kingdom. To render it such, Spain seems to have exerted all her strength, "as if, by this outward rind, she could conceal her interior weakness." The works were constructed under the directions of the celebrated Count Schaumburg-Lippe; and the fort, bearing his name, is considered a master-piece of the art. Olivenza, still closer to the frontier, is also a fortress, though not so strong. In this neighbourhood are also Villa Viçosa, a pleasant town, and a favourite country residence of the Portuguese monarchs, who have here a handsome hunting-park; and Portalegre, a handsome little town in a delightful country, with a good cathedral. Southward, in the interior, is Beja, a Roman colony, and subsequently a strong Moorish fortress. After being nearly demolished, it was rebuilt by Alfonso III., and fortified by King Diniz, and is still a considerable town.

2561. *Algarve* forms the extreme south of Portugal; and is a maritime province, bearing in an especial sense, the appellation of kingdom, since it long remained independent, and was a celebrated theatre of war between the Moors and the Christians. It is tolerably fertile in wine, fruits, and oil. Taro, the largest town, is also the principal seat of trade, and has a regular packet to Gibraltar. Lagos and Silves are also old little towns, the former on the sea-coast, with some shipping. Cape St. Vincent, the extreme point of Algarve, and the most south-westerly of the Peninsula, is celebrated for the signal victory gained by the British fleet over the Spanish, on the 14th of February, 1797.

2562. *Beira* is a very extensive province or kingdom, filling nearly the whole centre of Portugal, between the Tagus and the Douro. Its surface presents considerable variety; the interior part has the usual mountainous character of Portugal, being traversed by the great chain called the Sierra d'Estrella. On the sea-coast, however, there are plains of

considerable extent. The province produces plenty of wine, oil, and chestnuts, and has extensive pastures; but the grain is not sufficient for its consumption.

2563. *Coimbra* (*fig. 287.*), the capital, is beautifully situated on the declivity of a hill,

which rises above the Mondego; but the streets, as in other old Portuguese towns, are crowded, dirty, and very steep. In former times a residence of the kings of Portugal, it was strongly fortified, and has stood obstinate sieges; but the remains of its walls and towers are no longer sufficient to constitute it a fortress. It has been called the Athens of Portugal, from its extensive university, containing eighteen

colleges, with forty professors, and about eight hundred students. Attached to it is a library of nearly 40,000 volumes, including numerous MSS.; but the actual value both of these and the printed works does not seem to have been fully investigated.

2564. *Beira* has other towns of some importance. Among these is Almeida, the northern barrier of the kingdom and a fortress of consequence, though not possessing the great strength of Elvas. It was twice taken in the last war, first by the French under Massena, and then by the British under Wellington. Castello Branco, on the southern frontier, notwithstanding its commanding situation, retains little importance. Lamego, near the southern bank of the Douro, is an ancient city, and the cradle of the Portuguese monarchy. Here, in 1143, the states-general for the first time met, recognised the fundamental laws, and acknowledged the sovereignty of Alfonso. Viseu, in the centre of the kingdom, is, like Lamego, an episcopal see, and has the greatest annual fair in Portugal.

2565. *Entre Douro e Minho* forms the maritime part of Portugal, north of the Douro. Though the smallest, it is considered the most valuable, populous, and productive of all the provinces. Its peasantry have done much to redeem the reproach of torpor and sluggishness generally urged against their countrymen. This district is entirely covered with mountains, partly rugged and barren, but generally separated by fertile and well-watered valleys, cultivated to the utmost possible extent; and which, besides oil, fruit, and flax, are made to produce most copiously the wine called *port*, for which so ample a market exists in England.

2566. *Oporto, or Porto* (*fig. 288.*), the ancient capital, and still the second city of the kingdom, is situated near the mouth of the Douro on the northern bank, though on the southern are

two extensive suburbs, supposed to have constituted the ancient city. The modern town is well built, especially when compared with most others in the Peninsula. The river affords a tolerably secure harbour, without any artificial aid, except an elevated and walled quay, to which the ships' cables may be fastened during the floods. These often come down with such force, that, without such a support, the vessels would be inevitably carried out into the sea. The chief dependence of Oporto is its trade with England, which remains unimpaired amid the general diminution of that with America. There are about thirty English houses regularly settled here, besides a number of merchants who pay frequent visits to the place: The exportation of port wine, however, on which its trade rests, is generally cramped by

the absurd policy of placing it entirely in the hands of an exclusive company, who have adopted the pernicious practice of diluting the produce of the best vineyards with wine of those of an inferior quality, by which the character of the genuine port grievously suffers.

2567. *Braga*, farther north, ranks as the capital of the province; and, though now far outstripped by *Oporto*, is of much more ancient fame. Under the Romans it was the metropolis of an extensive district, and its former greatness is still attested by numerous antiquities. It has made a distinguished figure in the ecclesiastical history of Portugal, and is the see of an archbishop, who is primate of the kingdom. *Braga* is a handsome town; well built, well paved, the streets spacious and clean. There is some industry, particularly a manufacture of small beaver hats, which supplies a great part of the kingdom. The adjacent country is hilly, but populous and pleasant. *Valença* is a small town, agreeably situated on the *Minho*, which separates it from *Galicia*.

2568. *Tras os Montes*, or the province beyond the mountains, is of great extent, occupying the whole interior of Portugal south of the *Douro*. The Cantabrian chain, after traversing *Asturias* and *Galicia*, throws out branches which not only separate that territory from the rest of Portugal, but cover almost its whole surface. They leave only deep valleys, through which considerable rivers, too rapid however to be navigable, pour down into the *Douro*. It is much inferior to *Entre Douro e Minho*, both in populousness and cultivation; yet a considerable quantity of the port wine produced grows on the sides of its hills. The inhabitants are a race of active, hardy, and brave mountaineers. They rose in great force against the French, and have since somewhat less happily distinguished themselves by the ardour with which they fought in the cause of absolute power, and in resistance to every form of constitutional government.

2569. The towns are small, and not regularly fortified; though, from the nature of the country, they form defensible military positions. *Braganza* is a city of ancient note, and gave the title of Duke to the first nobleman in the kingdom, even before he was raised to the throne, by the appellation of John IV. The kings of Portugal still retain the title of Dukes of *Braganza*. *Chaves*, the *Aquæ Flaviæ* of the Romans, still exhibits two baths and a magnificent bridge constructed by that people. *Chaves* gives the title of Marquis to a family, one of whom was the most active opponent of the French during their invasion; while another has lately been at the head of the anti-constitutional army, of which the headquarters were always in *Tras os Montes*.

2570. The Arabs in Spain, like the Saxons in England, established a lasting memorial of their dominion by engrafting their own language on that of the country which they subdued. Of this, the topography of the Peninsula exhibits innumerable instances. The names of rivers, mountains, towns, and places, were either totally or partially changed, by the victorious invaders; and, after the expulsion of their descendants, those names were perpetuated, though with alterations in some instances as arbitrary as those which were made in the ancient topography of the country: thus, the Roman station, *Pax Augusta*, was transformed by the Arabs into *Batalio*, and afterwards by the Spaniards into *Badajoz*; *Cæsar Augusta*, by an abbreviation less violent, became *Saragossa*; and *Emerita Augusti* was contracted into *Merida*.

2571. The Arabic term *Medina* (city) survives in two eminent instances among the titles of the Spanish nobility: *Medina Selim* (the city of Selim) is recognised in the dukedom of *Medina-Celi*; and the colony probably called New Sidon, is that of *Medina-Sidonia*.

2572. From the generic term *guad*, a river, and *velex* or *veled*, a landed estate or district, many names may be explained which at first view appear capricious and arbitrary:—

<i>Ex.</i>	<i>Guad-al-aviar.</i>	The white river.
	<i>Guad-al-quivir.</i>	The great river.
	<i>Guad-al-higiara</i> , now <i>Guadalaxara</i> .	The river of rocks.

Velex and *Veled* are often conjoined with proper names, *Velex Malaga*, *Veled Vlid*, now *Valadolid*: thus *Navarre*, *Leon*, and their confines never having been occupied by the Arabs, were called by them *Veled Arroum*, the land of the Romans.

2573. *Gezira* was applied indifferently to an island or a peninsula; hence *Algezira*.

2574. *Aldea* means what is comprehended under the English term a farm. It is of common occurrence in itineraries, as *Aldea del Rio*, *Aldea Gallega*, *Aldeas de Fonsso*.

2575. From *cántara*, a bridge, we account for the emphatic name *Alcántara*. *Caláto*; a castle, enters more or less prominently into the composition of various names; as *Caláat Ayat*, the castle of *Ayat*, is now *Calatayud*; *Caláat Rabah*, the castle of *Rabah*, is now *Calatrava*; *Al Caláat*, simply the castle, is now *Alcalá*.

2576. *Alcazar*, a word of frequent occurrence in Spanish topography, is a fortified house or small castle; *Almeria* is an observatory.

2577. See *Description of Spain*, by Gerif Alhedris, in the translation of Don José Antonio Condé, whose *History of the Domination of the Arabs in Spain* is esteemed one of the most masterly works that have appeared in the present age.

CHAP. VIII.

ITALY.

2578. *Italy* is an extensive region in the south of Europe, one of the finest in the world as to soil and climate, and noted as the theatre of many of the greatest events in history. It is now in a state of degradation and decline, but is filled with grand monuments, and scenes calculated to awaken the most lofty recollections.

SECT. I. *General Outline and Aspect.*

2579. *Italy* is bounded on the north, and partly on the west, by the vast and continuous range of the highest Alps, which separate her from what she disdainfully terms the ultra-montane regions of France, Italy, and Switzerland. All the rest of her circuit is enclosed by the Mediterranean and its great gulfs, of which the Adriatic, in the east, separates her from the opposite shores of Greece and Illyria. On the west she borders on the broadest basin of the Mediterranean, beyond which are the shores of France and Spain. On the extreme south she almost approaches the African coast. The greatest length is north and south from about $36^{\circ} 40'$, or 700 English miles; the extreme breadth, between the Rhone in Savoy and the Isonzo, lies between 6° and 13° west longitude, and may comprehend 350 English miles. This applies only to the broad belt of Northern Italy, as all the rest of the territory stretches obliquely in the form of a long narrow boot, the average breadth of which does not exceed 100 miles. The whole extent may be reckoned at 117,090 square miles, including Sicily and Sardinia.

2580. *The surface of Italy* is the most finely diversified of perhaps any country in the globe. It has the loftiest mountains, and the most beautiful plains in Europe. All the chains of Alps, the Cottian, the Pennine, the Lepontine, the Rhætian, the Julian, which belong only in part to other kingdoms, range along her frontier. Some of their proudest pinnacles, indeed, Mont Rosa, St. Bernard, the Simplon, St. Gothard, Oerteles, are within the Swiss territory; but their white summits are seen amid the clouds in continuous grandeur along the whole extent of the plains of Lombardy and Piedmont. The Apennine is a chain purely Italian. It branches off first from the Maritime Alps on the western frontier, and runs for a long space eastward, leaving on the south only a narrow plain between it and the Mediterranean; while on the north it forms the boundary of Piedmont and Lombardy. On the Tuscan border it gradually bends round to the south and south-east, following, or rather prescribing the form of the Peninsula, of which it occupies the centre in one unbroken line. It does not aspire to the awful height, or wrap itself in the perpetual snows, of the Alps. Its highest pinnacle in the Abruzzo, called the great rock of Italy, does not rise above 9000 feet. These mountains are consequently, in this climate, throughout, covered with luxuriant foliage; on the lower slopes are the vine and the olive, higher up, the various forest trees, among which the chestnut affords copious food to the inhabitants. They enclose finely cultivated valleys, and are full of deep, intricate, and wooded defiles. As their branches, dividing into low hills of varied form, touch upon the fine plains along the Mediterranean, they produce a variety of bright and smiling scenes, which entitle Italy to be considered as the peculiar region of landscape. In the southern quarter they assume a very formidable and volcanic character, pouring deluges of burning lava from the cone of Vesuvius, and convulsing Calabria with the most terrible earthquakes. Their aspect in that country is peculiarly formidable and rugged (*fig. 289.*). Beyond the straits of Messina,

MOUNT ETNA.

height which only the Alps can surpass, while it throws out, amid the snows, volcanic eruptions as remarkable as those of Vesuvius.

2581. *The plains of Italy* are as remarkable for their extreme beauty as the mountains for their grandeur. The most extensive is that of the Po, or of Lombardy, between the Alps and Apennines, which, being profusely watered, highly cultivated, and under a genial climate, is, perhaps, the richest and most productive region in Europe. The Apennines, in their course southward through the centre of Italy, divide it into two plains, of which that

on the east is narrow, and often crossed by branches from the main ridge, which present their bold cliffs to the Adriatic. On reaching the Neapolitan territory, the plain becomes wider and more fertile, being covered with rich pastures and vast plantations of olives. But it is on the western side that Nature most profusely displays her beauties, and that the grand seats of civilisation and power have been established. The Tuscan champaign is scarcely considered as composed of more than two broad valleys, those of Florence and of Pisa; but the *Campagna Felice* of Naples, the voluptuous environs of Capua, appear to unite all the richness of Lombardy with aspects much more varied and picturesque, and are usually considered the most delightful country in Europe. All this side of Italy, however, is subject to a dreadful scourge, the *maremma* or pestilential influence arising from a marshy and swampy surface. The Pontine Marshes are in this respect so dangerous, that in the hot season they can scarcely be crossed, even hastily, without the peril of death. But it is

round the imperial city itself, and at its very gates, that the maremma appears peculiarly desolating. The campagna of Rome, which cultivation and draining rendered formerly one of the finest spots of Italy, has, under the present proud and indolent rule, been so far neglected, that the pernicious influences of its low and swampy soil have gained a fearful ascendancy. They have rendered it uninhabitable for a great part of the year; and this "storied plain" is become a desert, covered with a few scanty herds; and a deep solitude now encircles the fallen metropolis of the world.

2582. *The rivers* of Italy scarcely correspond to their fame, or to the lofty and classic recollections attached to their names. The Po, which waters the plain of Lombardy, and drains all the waters of the Alps and northern Apennine, can alone be ranked among the great rivers of Europe. It rises on the frontier of France, amid the loftiest recesses of the Cottian Alps, and rolls due west the whole breadth of Italy to the Adriatic, a course of about 400 miles. Its tributaries on both sides are very numerous, though none have space to expand into great rivers. The alpine streams of the Tesino, the Adda, and the Oglio, are absorbed soon after they have left their deep mountain valleys or lakes. The Adige makes its way entirely over from Germany in the valley between the Rætian and Julian Alps, and falls into the Adriatic not far from the Po. These rivers being always full, and crossing the main line of communication, form important military barriers. They preserve also the plain in a state of perpetual fertility, though they often cause considerable calamity by their inundations. The tributaries from the south are also numerous, but, with the exception of the Tanaro and the river of Genoa, of no remarkable magnitude. The rivers of Lower Italy would scarcely deserve mention, but for the high associations of history and poetry. The far-famed Tiber itself, which on this ground, "with scorn the Danube and the Nile surveys," is described by Addison as deriving its scanty stores from an unfruitful source. It drains, however, a considerable extent of the Apennine, and its entire course may be 150 miles. The Arno of Florence and the Lirio of Campagna are only distinguished for the beauty of the vales through which they meander.

2583. *Lakes* are not a feature very characteristic of Italy. Nevertheless, the waters which descend from the southern face of the Alps, spread into the long and winding lakes, Maggiore, Como, and Garda, which extend into the plain of Lombardy. The scenery of these lakes has not the grand and solemn character of those of Switzerland, which are enclosed in the depth of the highest Alps; but they are beautiful in the extreme. The lower banks are bordered by gentle hills covered with vines and luxuriant verdure; while their heads are crowned by the snowy summits of the Alps. The Apennine is not a lake-producing chain; it only forms on its eastern border a few that are small, and very beautiful, Perugia, Celano, Bolsena, &c.: Sicily is also without lakes.

SECT. II. *Natural History.*

SUBSECT. 1. *Geology.*

2584. *The geognosy* of this country has, of late years, engaged the particular attention of naturalists; consequently, numerous new facts and views have been added to those formerly known. The writings of Dolomieu, Hamilton, Von Buch, Spallanzani, Brocchi,

Breislac, Brongniart, Hausmann, Daubeny, Monticelli, Covelli, &c. are among the most interesting with which we are acquainted as illustrative of the mineral history of Italy and its islands; and to these we refer our readers. The following observations will convey a general idea of the geognostical structure and composition of this interesting country.

2585. *The geognostical structure* of the central part of the Apennines is very simple; the mountains of that division of the range being composed of a white limestone which rarely contains foreign beds, and but seldom fossil organic remains. It is there, too, that the range is loftiest, and is also the broadest. But this simplicity of construction does not continue throughout the whole Apennine range; for, from the point where it rises from the Alps to the country of Florence, it is composed of strata and beds of slate, limestone, and a magnesian rock, named in Tuscany *gabbro* and *granitello*. The summits of the mountains of the country of Genoa, which overlook the Gulf of Spezzia, are principally formed of this latter substance, which is the *euphotide* of geologists. Some geologists consider this part of the range as of primitive formation; while others, as Professor Hausmann, view it as belonging to the transition class of rocks, because he finds it containing, intermingled with the rocks just mentioned, extensive deposits of greywacke. A limestone, resembling that of the Jura, forms all the mountains extending from Florence to Abruzzo, and from Abruzzo to Calabria. It is only in the latter province that the central part of the chain is formed of granite, gneiss, mica slate, and other primitive rocks; resting upon which, in the lower parts of the country, there are deposits of tertiary rocks.

2586. *The sub-Apennine hills* belong to the tertiary series, and are composed of marls, slate clays, gravel, sands, and conglomerates. We observe also in these hills, but less frequently, gypsum, calcareous tuffas, and volcanic tuffas. A limestone of modern formation abounds in the neighbourhood of Rome, and is known under the name *travertino*, and of which the principal monuments of that city are built.

2587. *The Apennines are not rich in metals.* The most considerable mines are those of *iron*, which occur in Tuscany, and chiefly in the island of Elba, a tract composed of primitive rocks. The *coal mines* in this chain are of but little importance, but there are great deposits of *salt* in the province of Cosenza. The principal mineral treasures of the Apennines are the *marbles*, of which the most celebrated are those of Carrara, Seravezza, and Sienna.

2588. *Ancient volcanoes* do not occur in the central part of the Apennines; all of them, with one exception, the hill of Voltore, near to the town of Melfi, in the province of Basilicata, are situated on the south-western declivity of the chain. They form an interrupted chain, which is passed over on the road from Sienna to Rome. The most elevated spots of this district, such as the Monte Cimini near Viterbo, and the Monte Amiata, appear composed of trachyte. It is associated with basalt at Viterbo, where it is columnar, and rests on a bed of pumice and tuffa, containing the bones of quadrupeds. Near Viterbo is a small lake which is in a constant state of agitation, owing to the emission of sulphuretted hydrogen gas; and a little nearer, on the road to Rome, is the Lake of Vico, formerly the Lacus Cimini, which has all the appearance of a crater. The Lake of Bolsena, between Viterbo and Sienna, possesses the shape of an ancient crater, and its being bounded by volcanic rocks is consistent with this opinion. The country around Rome, and also the hills on which the city is built, is composed of tertiary marls, clays, and sandstones, intermixed with a preponderating quantity of granular and lithoidal volcanic tuffas. The marls and sandstones are partly lacustrine, partly marine. The many lakes around Rome, such as those of Albano and Nemi, are formed by craters of ancient volcanoes. In the vicinity of Modena there are many small *mud volcanoes*, called *salses*, which throw out salt water. These volcanoes give out carbonated hydrogen, which, sometimes catching fire, gives rise to the *natural fires* mentioned by travellers, of which there are examples at Velleja, Pietra Mala, and Barigazza. On the road between Rome and Naples, the first indication of volcanic action, after passing the Pontine Marshes, occurs a little to the south-west of Mola de Gaeta. We there find ourselves between two chains of hills,—that to our right, the Monte Massico, composed of Jura limestone; the other, on the left, of volcanic marls. The town of Sessa stands on volcanic tuffa. Several *coulées*, or streams of lava, which seem connected with the volcanic hill of Rocca Monfina, also occur near Sessa. Rocca Monfina retains the vestiges of the great crater from whence these coulées flowed. A few miles west of the Mola de Gaeta lie the *Ponza Islands*, four of which are composed of trachyte; in the fifth, Giannone, the trachyte overlies limestone.

2589. *Vesuvius.*—The only active volcano in Italy is Vesuvius, which shoots up in a country where the surrounding Neptunian strata belong to the tertiary class. It is composed of an older part, named Monte Somma, and the more modern Vesuvius properly so called. Somma is composed of alternating coulées, or streams of lava, and beds of volcanic tuffas, which are traversed by veins or dykes of lava. The modern part of the mountain is Vesuvius, exhibiting rocks of the same general description. The earliest recorded eruption of Vesuvius is that of 79, during which so vast a shower of ashes and scorïæ was thrown out, that the cities of Stabiæ, Pompeii, and Herculaneum were covered up, indeed fairly buried, by it. Many eruptions have taken place since that period, and they still continue.

In the country around Naples the land is by no means stable, as is proved by the submergence and emergence of the Temple of Serapis, near the town of Puzzuoli; and the rise of a new mountain, on the northern side of the bay, in the sixteenth century. Vesuvius had at that time been for a long interval tranquil, but a succession of earthquakes had taken place in the country for two years previously: at length, on the 28th of September, of the year 1538, flames broke out from the ground between Lake Avernus, Monte Barbaro, and the Solfatara, followed by several rents of the earth from which water sprung, while the sea receded 200 feet from the shore, leaving it quite dry. At last, on the 29th, about two hours after sunset, there opened near the sea a gulf, from which smoke, flames, pumice and other stones, and mud, were thrown up with the noise of thunder. In about two days the ejected masses, formed a hill 413 feet high, and 8000 feet in circumference. The eruption finally ceased on the 3d of October. On this day the hill was accessible, and those who ascended it reported that they found a funnel-shaped opening on the summit—a crater a quarter of a mile in circumference. This hill, named *Monte Nuovo*, is composed of fragments of scoriform matter, or of a compact rock of an ash grey colour, sometimes resembling trachyte, and at other times approaching to porphyry and calx.*

2590. *The nearest approach to the phenomena of Vesuvius* is exhibited in a hill between Monte Nuovo and Puzzuoli, called the *Solfatara*, which, though considered an extinct volcano, is continually giving off gaseous exhalations mixed with aqueous vapour. The gases are sulphuretted hydrogen and muriatic acid. The rock of the hill is trachyte. A vast coulée of trachytic lava appears extending from the Solfatara to the sea, forming the promontory called the Monte Olibano, on the road between Naples and Puzzuoli. The whole of this stream rests upon the extensive formation which reaches from Puzzuoli to Cumæ, and appears to be continuous with the rock found in the immediate neighbourhood of Naples. This, which has long been known by the name of *Puzzuolana*, is a formation of volcanic tuffa. The height of the tuffa, in many places near Naples, is very considerable; the pile of the Camaldulo, the loftiest eminence next to Vesuvius in the whole country, is composed of it, and to the west of Naples it forms a sort of wall, so lofty and abrupt, that the former inhabitants of the country apparently found it easier to avail themselves of the soft and friable nature of the stone, and to cut through, than to make a road over it. This is the origin of the celebrated *Grotto of Posilippo*; a cavern 2178 feet in length, 50 feet in height, and 11 in breadth. The *Lake Agnano* occupies the crater of an old volcano. The famous *Grotto del Cane*, situated on its borders, is perpetually giving out carbonic acid gas, containing in combination much aqueous vapour, which is condensed by the coldness of the external air; thus proving the higher temperature of the place from whence it proceeded. The mouth of the cavern being rather more elevated than its interior, a stratum of carbonic acid goes on constantly accumulating at the bottom, but, upon rising above the level of its mouth, flows like so much water over the brim. Hence the upper part of the cavern is free from any noxious vapour; but the air of that below is so fully impregnated, that it proves speedily fatal to any animal that is immersed in it, as is shown to all strangers by the experiment with the dog. The *Lake of Avernus* may likewise have been the crater of a volcano. The Monte Barbaro is probably the most elevated volcanic hill on this side of Naples: it has a crater on its summit, and its great antiquity is shown by the circumstance of its surface being covered with verdure. The perfect condition of the crater of Astroni has caused it to be selected by the King of Naples as a preserve for his wild boars and other animals destined for the chase: it is a circular cavity, nearly a mile in diameter, the walls of which are formed of a congeries of scorix, pumice, and other ejected materials. According to Breislac, the number of craters of which indications occur in the neighbourhood of Naples will amount to not less than 27; but we suspect the amount is much over-rated.

2591. *The middle and lower parts of the river district of the Po* is formed of tertiary rocks more or less deeply covered with diluvium. The tertiary deposits are intermingled in a very interesting manner, on the southern foot of the Lombard Alps, with various trap rocks. These arrangements are best seen at the following places:—in the Val Nera, Val Ronca, Montecchio Maggiore, Monte Viale, and Monte Bolca. South of Padua lie the Euganean hills, an isolated track of high ground, in the midst of a level tertiary country; consisting of a trachyte formation, not unlike that of Hungary, which, from its vesicular structure in some cases, and its semivitreous appearance in others, would at once be taken for a volcanic product. The tertiary deposits contain remains of whales of extinct species, also of the elephant, rhinoceros, hippopotamus, &c.; and fossil animal remains of the same description occur more abundantly in the diluvium. Tertiary and diluvial deposits also extend from Ancona along the coast of the Adriatic, with but little interruption, to the extremity of the Peninsula.

2592. *Italian Islands.*—*Islands of Procida and Ischia.* These islands are situated a short distance from Naples, and are entirely of volcanic formation. *Procida* consists of an alternation of beds of tuffa and of slaggy lava. *Ischia* is composed for the most part of a rock which seems to consist of finely comminuted pumice, re-aggregated so as to form a tuffa.

* Daubeny.

2593. *Lipari Islands.* The Lipari Islands, between Naples and Sicily, are also composed of volcanic rocks. The island of *Stromboli* consists of a single conical mountain, having on one side of it several small craters, one of which is in a state of activity, the rest extinct. This volcano is remarkable, not for the intensity of its action, but for the circumstance of rarely enjoying periods of repose, no cessation in its operations having been observed from a period antecedent to the Christian era. Its action consists in ejections, repeated at very short intervals, of stones, scorix, and ashes, which either fall back within the crater, or are carried in another direction, according to the drift of the wind. The island abounds in volcanic tuffa, which is traversed by dikes of slaggy lava. The island of *Lipari* is remarkable for its splendid displays of the beautiful volcanic glass named *obsidian*; and for a profusion of pumice. The pumice of commerce is principally obtained in that island. Another isle of the Lipari group is *Volcano*, which appears, prior to the Christian era, to have been in a state of activity at least equal to that of *Stromboli*, and which still emits gaseous exhalations from the interior, as well as from several parts of the external surface of a crater situated in the highest part of the island. These vapours, acting upon the rock they penetrate, decompose it, and form with its constituents large quantities of *alum* and other sulphuric salts. This island also affords a very rare substance, viz., the *boracic acid*, which lines the sides of the cavities in beautiful white silky crystals, and combined, it is said, with ammonia. *Sal ammonia* also occurs in this curious spot; and in a mixture of this salt with sulphur the substance named *selenium* has been detected. Close to *Volcano* is an isolated rock called *Volcanello*, which, though without a crater, emits from its crevices vapours of a sulphureous nature.

2594. *Corsica.* The mountains of this island are principally primitive and transition, the rocks being granitic and ophiolitic. Their limit, ranging nearly from S. to N., passes near to, and to the west of the town of Corte. All that is to the west of this line is in general granitic, with subordinate rocks of porphyry, gneiss, mica slate, and limestone or marble. To the east of the same line, all the N.E. of the island is principally formed of talc slate, containing numerous subordinate beds of marble, euphotide, slate, &c. Jura limestone appears at the bottom of the Gulf of Saint Florent, and on the east coast, to the north of the Gulf of Porto Vecchio. No volcanoes occur in this island; and the ancient lavas mentioned by some authors are beds of euphotide. Hot springs, however, occur in Corsica; the principal ones being those of Orezza, St. Antonio di Guagno, and Fium' Orbo. The only mines are those of iron, copper, antimony; and argentiferous galena is also met with, but not in such quantity as to be of any importance in an economical view. Considerable deposits of diluvium occur in different parts of the island; and these, like other formations, are more or less deeply covered with alluvium.

2595. *Sardinia.* The predominating formations in this island are primitive and transition; the rocks being granite, mica slate, clay slate, and limestone. On the north-western part of the island there is a considerable deposit of tertiary limestone, and one of much greater dimensions in the southern division. Trachyte and other volcanic rocks appear in connection with the tertiary deposits; and Mr. de la Marmora observed extinct volcanoes on various points, and principally in the chain of mountains which extends across from the canton of Marghine from Milis to Bollotana. All these districts, of igneous origin, exhale pestilential vapours, which may assist in explaining the remarkable unhealthiness of this island. Caves occur in the limestone; and these, with the rents that traverse it, contain, generally embedded in a kind of breccia, bones of various kinds of quadrupeds, some of living species, but the greater number of animals which appear to be extinct. Metals are rare; there are but feeble traces of silver, copper, and mercury. Many mines, however, of lead and iron occur.

2596. *Sicily.* In this remarkable island the predominating rocks are tertiary, secondary, and volcanic; the older ones, or those of the primitive class, being less abundant. The primitive rocks are found at the north-east corner of the island, near Messina, where the prevailing kind appears to be gneiss. The transition constitute a chain of hills extending obliquely from Melazzo on the north coast, to Taormina on the east. They consist chiefly of mica slate, clay slate, with beds of glance coal, quartz rock, greywacke, sandstone, and limestone. Nearer than these is a great deposit of *sandstone*, with a few subordinate beds of marl and limestone, which occupies a great part of the central chain of the island, and extends along part of the northern coast. It first occurs to the east of Palermo, near the river Pilato, a few miles from Cefalu. It is older than the Jura or Apennine limestone. Resting apparently upon this sandstone is a formation of *limestone* and *dolomite*, composing the north-western part of the island, and which appears as the equivalent of the Jura or Apennine limestone. Caves containing bones occur in it. Resting upon this formation is a deposit of *marls* and *limestones*, containing nummulites and hippurites, which appear to belong to the chalk and green sand of English geologists. Upon these rest a series of *cretaceous limestones* and *marls* of the *older tertiary* epoch. The fifth formation is an extensive tertiary limestone, found both north and south of the grand central range. Above this rests a still newer deposit of a conglomerate, containing shells of species now existing in the Mediterranean: it is well seen on the north coast, and to the south of Syracuse. Of the same age with this deposit is

a *bone breccia* which forms beds lying upon the preceding, and also occurs in caves ; and in both situations contains bones of the elephant, hippopotamus, and deer, with a few of a carnivorous animal of the genus *Canis*. Still newer than this bone conglomerate is a diluvial deposit ; of which there are two kinds : the oldest occupies considerable heights, the newest covers the bottom of valleys. The tertiary rocks, so abundant in the island, contain beds of *common salt*, *sulphur*, *gypsum*, *alum*, along with beautifully crystallised *sulphate of strontites*. Volcanic action appears to have been in operation from a very remote period in this island, as is evinced by the different sets of volcanic rocks which Etna affords. The oldest volcanic rocks of Etna are those in the Valle di Bove, where there is a magnificent display of trachyte, porphyry, and tuffa : the next in point of age are the basaltic rocks ; and the newest of all are the coulées or streams of modern lava, with their tuffas, ashes, sands, and scorïæ. The trachyte and basalt seem to have been produced before the commencement of the present order of things, the coulées, &c. are the matters which have flown within the period of human history, and which still continue. It is probable that this mountain was burning at a period antecedent to the time of Homer. At Macaluba, a hill near Girgenti, consisting of blue tertiary clay, there is a continual disengagement of carbonic acid and carbonated hydrogen, from small cavities, shaped like craters, which are filled with muddy water mixed with mineral oil. When the quantity of gas emitted is great, it throws up the mud to the height of 200 feet : these are called *air volcanoes*.

2597. *Sicily is not rich in metals* : the mountains to the N.W. of Taormina present traces of a *gold mine*, said to have been worked at a very remote period. Some mines of *silver*, *copper*, *lead*, and *iron* are mentioned. Beds of *sulphur* occur abundantly in the blue tertiary clay ; and though Sicily has long supplied Europe with that mineral, its stores are yet far from being exhausted. The blue clay also contains beds of *rock salt*, of which the most considerable are at Alimina, N.E. of Castro Giovanni, where this substance is found both massive and crystallised.

2598. *Malta and Gozo*. These isles consist entirely of tertiary rocks, closely resembling those of the south-eastern part of Sicily. The most common rock is a fine-grained straw-coloured limestone, which is often so soft as to be worn down rapidly by the weather ; but in other instances, it is sufficiently hard to form an excellent building stone, to which circumstance these islands have been in a great measure indebted for the elegance of the numerous churches and palaces which are seen in every town and village. Harder and more crystalline limestones are also met with, but all of them are nearly of the same colour. Both these islands are of trifling elevation ; the highest point of Malta, which is one of the hills to the west of Cività Vecchia, being only 590 feet above the level of the sea.

SUBJECT. 2. Botany.

" The garden of the world, fair Italy !
Thy very weeds are beautiful, — thy waste
More rich than other climes' fertility ! "

2599. *Italy and Sicily*. — These countries partake very considerably of the general character and aspect of the vegetation of the south of France ; and the geographical distribution of the plants is well depicted by M. Mirbel.

2600. *The Sicilians* cultivate, with more or less success, the Sugar-cane, the Custard-apple, the Date, &c. The different enclosures are surrounded by the *Agave americana*, which forms an impenetrable fence. By the side of the Plane, Poplar, and Willow, grow the Cactus Tuna or Prickly Fig, the Orange, Citron, and Olive, the Myrtle (*fig. 293.*), Laurel, Carob tree, and Pomegranate (*fig. 294.*) ; while *Arbutus*

MYRTLE.

POMEGRANATE.

and Tamarisk abound upon the coasts. The Dates of the environs of Girgenti, situated on the southern coast, are said by Mirbel to be excellent ; not so in the vicinity of Palermo, where the Date Palm is unknown except in gardens.

2601. *Of all the mountains of Sicily, Etna, whose enormous volcanic mass rises to the height of more than 10,900 feet, is the most celebrated. Its base, whose circuit exceeds 80 miles, exhibits all the fruit trees peculiar to the transition zone: higher up is the forest region. It is said that two or three centuries ago this region ascended to the very summit: however this may have been, it now ceases at a considerable distance from it. The most remarkable trees there are the Oak (*Quercus Robur*), the Beech, the Ash, Horsechestnuts in the greatest abundance, and Plum trees: higher up are woods of Birch. These last, which form the upper zone, are scanty on the southern side, and very numerous on that exposure of the mountain which looks towards the north. Beyond this region every thing green disappears, and the only shrub is *Spartium etnense Bivona*. Mount Etna has no perpetual snow, unless we so consider those masses which lodge in shaded crevices, and there resist the heat of summer, at an elevation of nearly 9000 feet.*

2602. *It is well ascertained by geological facts, that Sicily and Italy once composed but a single continent, and that the mountains which cover so large a portion of the former, are but a continuation of the southern chain of the Apennines, which, interrupted by the Straits of Messina, re-appears in Calabria, and lifts its loftiest summits in the kingdom of Naples. Though some of these rise to 8000 feet, the snow nowhere remains permanently upon them. It is only in the southern part of Italy that the Apennines can boast of a rich vegetation; every where else this chain is of an arid and sterile character.*

2603. *The temperature of Calabria has much affinity with that of Sicily: its summers are intolerably hot, and frost is scarcely known during the winter. The numerous rivers and brooks which gush from the hills, abundant dews, and an astonishingly fertile soil, maintain, during almost all the year, in these favoured countries, a fresh and brilliant verdure. The plains, the slopes and eminences, produce Olives, Tamarisk, Arbutus, Myrtle, Jujube, Pistachios of both kinds, and Oleander (only in dry beds of torrents), the Sweet Bay, and Carob, the Palmetto, Rhamnus, and Phillyrea; the *Pinus Pinea* or Stone Pine (*fig. 295.*), — the tree, whose picturesque outline and dark hue have recommended it so much to the artist, that it forms a striking feature in almost all Claude Lorraine's and Gaspar Poussin's celebrated Italian landscapes; Manna Ash, Chestnut, Mulberry (*fig. 296.*), Plane, Willow, and Poplars, &c. In the warmer spots there are large groves of Orange and Lemon trees; those of the vicinity of Reggio being most esteemed. In the fifteenth century, the cultivation of the Sugar-cane was carried on with spirit in Calabria, and even on the coasts of Samnium: now, the red and white mulberry, which are grown for the silkworms. The barren rocks are covered with Agave, Cactus, and Capers.*

2604. *That portion of the Apennines which intersects Calabria is clothed from the base to the very summit with umbrageous forests of Oaks and Coniferous trees: especially consisting of the Common Oak, the Cork tree, the *Quercus Cerris*, Horsechestnut, and Yew, the Larch and Wild Scotch Fir, with the Pinaster, &c.*

295

STONE PINE.

296

MULBERRY

2605. *Most of the vegetable productions of Calabria follow the line of the coast, and adorn the shores of the bays of Naples and of Gaëta. The Orange and Lemon reach the Gulf of Genoa, but the climate refuses to perfect the Sugar-cane. The French tried in vain to naturalise it, during the period of their sway in Italy. Snow rarely falls in Naples; still, instances of its having been seen for a few days are not unknown. Judging by the state of vegetation, the average heat at Naples is about one degree higher than at Rome. Winter begins in December; the first spring flowers are expanded by February; and in May the summer heats are already felt.*

297

MILLET.

2606. Throughout the country in general, besides Maize, and Millet (*fig. 297.*), here, as in all the warmer parts of the northern hemisphere, Rice (*fig. 298.*) is extensively cultivated, especially in low flat lands, where the fields can be temporarily inundated. This operation, as may be supposed, occasions much pestilential fever; so that, in many districts of Italy, laws are enacted prohibiting rice-grounds within the distance of five miles from the large towns. *Arundo Donax* (*fig. 299.*) is a gigantic grass, frequent in Italy, which seems to take the place of our Common Reed (*A. Phragmites*). Of the *A. Donax*, fences are made, also walking-canes, fishing-rods, and a variety of articles which require strength combined with lightness. The Caper (*fig. 300.*) of commerce, too, is an object

298

RICE.

of considerable value. It is the *Capparis spinosa* of Linnæus, the Cappai or Kappai of the Arabians. It grows upon old walls, and in dry rocky situations. The buds of the flowers are gathered before expansion, put into vinegar, and, as is well known, are extensively employed in seasoning for various dishes.

299

ARUNDO DONAX.

300

CAPER.

2607. There is a wide difference between the temperature of the more northerly and the southern provinces of Italy; owing as much to the increased height of the Apennines and their broader bases, as to the actual elevation of latitude. Beyond Samnium, the Orange and Lemon can no longer endure the climate. The plains of Abruzzo sometimes experience cold winters; and though the Oaks are seen on the sides of the mountains, they no longer reach their tops, and the Coniferous trees are as scarce here as they are abundant in Calabria. The *Pinus Pumilio*, which of all the genus is the one that grows at the greatest height, stops at 4800 feet; beyond it are only seen such shrubs, plants, and herbs as are peculiar to regions where the snow regularly falls during the whole winter.

2608. The Olive tree, and its common accompaniments, reaches to Rimini on the eastern coast, where the salt-marshes, perhaps, arrest its further progress equally with the colder temperature; on the western side it attains to the bases of the Pyrenees; and near Padua, in latitude 45° , and in sheltered spots about the lakes of Garda and Como, it also grows. At Verona, this tree is no longer seen: but the Pistachio, Pomegranate, *Zizyphus vulgaris*, *Diospyros Lotos*, *Celtis australis*, and *Ostrya vulgaris* are in abundance.

SUBJECT. 3. Zoology.

2609. *The zoology of Italy*, the garden of Europe, is peculiarly interesting both to the classic traveller and the scientific naturalist: its rich and sunny plains, intersected by wooded hills, and backed by the noble chain of the Apennines, terminated only by the sea, presents that diversity of temperature and situation so well suited to display a rich and varied assemblage of native animals. Hitherto this zoological field has been but imperfectly explored: hence it becomes extremely difficult, if not impossible, to give more than a slight and very general sketch of its leading peculiarities.

2610. *The native quadrupeds* have never been particularly enumerated; but wolves are still found among the Apennines, and the wild boar is not unknown in the forests of Calabria. The buffalo was once employed as a beast of burden, but is now rarely if ever seen; nor can it be numbered among the native animals.

2611. *The ornithology of central Italy* has very recently been ably illustrated by the Prince of Musignano (Ch. L. Bonaparte). Information from such a source is so highly valuable, as throwing so much light on the general distribution of the European birds, that we shall here introduce the results furnished by this eminent ornithologist.

2612. *The number of species* discovered in the vicinity of Rome, and which probably includes nearly all those found in the States of the Church, amount to 247: of these, 60 are also found in America; leaving 187 as exclusively belonging to the European fauna. The whole 247 species are arranged under the following heads:—stationary near Rome 43; permanent residents, but occasionally changing their station, 37; summer visitors, 40; winter visitors, 57; transitory visitors, 26; accidental visitors, or stragglers, 44.

2613. *The following list of Roman birds*, unknown as natives of Britain, will materially illustrate the geographic ornithology of the two countries; those marked * have occasionally been found, as stragglers only, in our islands:—

Cathartes percnopterus.	Slender-billed Vulture.
Falco naevius.	Rough-footed Eagle Lath.
Falco brachydactylus.	Short-clawed Falcon.
— Cenchris Bonap.	Little Kestrel.
— rufipes Tem.	Rufous-thighed Falcon.
Strix Aluco.	
Pastor roseus.*	Rose-coloured Ousel.
Oriolus Galbula.*	Golden Oriole.
Coracias garrula.*	European Roller.
Cypselus melba.	Alpine Swift.
Muscicapa albicollis.	White-collared Flycatcher.
Lanius meridionalis.	Southern Shrike.
— minor.	Italian Shrike.
— rutilus.*	Woodchat.
Merula cyanea.	Blue Thrush.
— saxatilis.	Rock Thrush.
Curruca turdoides Sw.	Thrush Sedgebird.
Sylvia ignicapilla.	Fire-crested Warbler.
Sylvia Cetti Tem.	Cetti's Warbler.
Sylvia melanocephala Lath.	Black-headed Warbler.
Sylvia cisticola Tem.	
Sylvia passerina Tem.	
— Tithys* Tem.	
— sibilatrix.	
— rufa.	
Saxicola strapazina.	
— aurita.	Golden Stonechat.
Anthus aquaticus.	Water Titlark.

Anthus rufescens.	Rufous Titlark.
— arboreus Bech.	Wood Titlark.
Tichodroma muraria.	Wall Creeper.
Upupa Epops.*	European Hoopoe.
Parus pendulinus.	Pendulous Titmouse.
Alauda Calandra.	
— cristata.	Crested Lark.
— brachydactyla.	Short-clawed Lark.
Emberiza cia.	
Fringilla cisalpina.	
— Serinus.	
— petronia.	
Perdix saxatilis Tem.	Rock Partridge.
Charadrius minor.	Little Plover.
Ciconia alba.	White Stork.
— niger.	Black Stork.
Ardea purpurea.*	Purple Heron.
— ralloides Scop.	Rail Heron.
Ibis falcinellus.	European Ibis.
Numenius tenuirostris.	Slender-billed Curlew.
Tringa subarquata.	
Totanus stagnatilis.	Pond Sandpiper.
Platalea leucorodia.	Spoonbill.
Phoenicopterus antiquorum.	Flamingo.
Sterna leucopetra.	White-winged Tern.
Anas leucocephala Lath.	
— leucophthalmos Tem.	
Pelecanus Onocrotalus.	White Pelican.

2614. *It must nevertheless be remembered*, that this list, numerous as it is, exhibits but a partial statement of Italian ornithology; as the birds of the western and southern provinces, as Naples, Calabria, and Taranto, still remain to be investigated.

2615. *A brief notice of the most remarkable birds* will satisfy the general reader: these appear to be the Slender-billed Vulture, the Rose-coloured Starling, the Blue Thrush, the Hoopoe, and the Wall Creeper.

301

ROSE-COLOURED STARLING.

2616. *The Slender-billed Vulture* (*Cathartes percnopterus*) is near two feet and a quarter long: its principal food is carrion: hence the bill is not adapted for vigorous offence against living animals; the face is bare of feathers, while those on the neck are pointed. The general plumage is pure white, except the quill-feathers, which are black. In Europe, this vulture is confined to the southern kingdoms, but is abundant in Egypt, where it is of essential use in devouring all putrid substances, which might otherwise infect the air. The *Rose-coloured Starling* (*Pastor roseus*) (fig. 301.) is one of the most elegant birds of Europe; it is about the size of a thrush. The general plumage is rosy; the wings, and a pendent crest on the head, are glossy black. This bird has occasionally been seen in Britain, and, although widely dispersed over the greater part of Europe, it is nowhere so plentiful as in Asiatic Russia. The Blue and Rock Thrushes are sweet songsters, and on that account are much prized, when in captivity, by the Italians. The Hoopoe, so rarely seen with us, is one of the common migratory birds; it usually arrives from the African coast very flat, and we can, from experience, state it to be delicious eating when cooked in the Italian mode. The *Little Wall-creeper*, *Tichodroma muraria*, with its crimson wings, is one of the rarest birds, but is occasionally seen on the lofty walls of St. Peter's Church.

2617. *Among the insects of Italy*, the Tarantula Spider and the Silkworm are equally celebrated. So much of fable and exaggeration has been mixed up with the history of the first,

302

SCORPION.

that it is difficult to separate truth from falsehood: it is even doubtful whether any spider of a decidedly venomous character truly exists in the country. During a residence of many years in different states of Italy, we never met with one answering such a description; and it is well known that the common people give this name indiscriminately to every large spider they happen to meet with. Much more real danger may be apprehended from a species of true Scorpion, which is by no means

uncommon in damp houses; and our own specimen (*fig. 302.*) we actually found one evening within our bed: its sting is venomous, and, we have heard, dangerous. May not the qualities of this insect have been exaggerated, and transferred to a spider? The Silkworm is too well known to require description. In some provinces, as Lower Calabria, &c., the insect is fed more upon the leaves of the red than on the white mulberry. It is not generally known that a species of true *Termites*, or White Ant, inhabits Sicily; it is found only in old houses: upon one occasion we discovered a nest established in a portmanteau of clothes, most of which had been destroyed by the perforated labyrinths of these destructive creatures.

2618. *The domestic animals* are not very remarkable; the climate, from its heat, being ill adapted for grazing. The common breed of oxen are among the largest known, and are furnished with horns of an immense size; but the animals are gentle, and much used for draught: there is also another race, principally found in Tuscany, much smaller, and esteemed for its fine form and pure white colour; and these are exported both to Cuba and Jamaica. The insufficiency of pasture accounts for the scarcity of sheep; and this is so remarkable, that in some of the distant provinces mutton is considered rather unwholesome, and is rarely, if ever, brought to market. During many years' residence in southern Italy, we never saw this meat exposed for sale; and in the island of Sicily sheep are nearly unknown. In the southern provinces the cheese, butter, and milk is derived from goats, which are kept in flocks of 100 or 150: they are driven out in the morning by the goatherd, and conducted to their pens towards sunset. The pigs are all of the long-legged, unimproved breed, and no care is taken in their fattening.

2619. *Sicily.* *The zoology of Sicily* has been hitherto so little known, that we shall take this opportunity of briefly illustrating its peculiarities. The following remarks have been the result of personal observations, made during a long residence in this celebrated island.

2620. *The native quadrupeds*, in former times, appear to have been much more numerous than they are at present: this diminution has not originated in the increase of population or of agriculture, for both of these, it is well known, have enormously retrograded since the splendid epoch of Sicilian history. The diminution of the larger animals originates in two causes: first, the scarcity of wood and shelter; and, secondly, the universal passion for shooting. The ancient forests of Sicily, which once sheltered the larger game, have been gradually diminishing; and the next century may possibly witness their total disappearance. The only fuel burnt throughout the island is wood and charcoal. Now, a Sicilian landed proprietor never thinks of planting any other trees than vines or olives; to benefit his estate for the sake of those who are to inherit it afterwards, never enters his imagination. With such a constant and universal demand for fuel, and with no measures being taken to provide a future supply, it may therefore be easily imagined that wood is already scarce. The vast forests of Etna, of which so much has been said, and which originally belted that stupendous mountain, have been so diminished in modern times, that they hardly exist but in name. In these regions immense quantities of charcoal are made, and sent to all parts of the island. Trees are felled every day, but not one is ever planted; in short, even in 1815, after the British troops had been in the island ten years, wood began to be so scarce, that their rations of fuel were principally brought from the opposite shores of Calabria.

2621. *The scarcity of wild animals* originates also in another cause: every Sicilian peasant carries his gun as constantly upon his shoulder, as he does his cap upon his head; and he shoots at every thing. With but little shelter for retreat, or for breeding, and perpetually exposed to destruction by the gun, it is not surprising that Sicily in general should be as remarkable for its paucity of resident birds and quadrupeds, as it is for its naked unwooded appearance. Its scenery is grand and magnificent; but every where it is deficient in wood and water.

2622. *In former times, it appears that several wild animals*, now seldom if ever seen, were met with in abundance. Authorities cited by Mongitore (*Sicilia Ricercata*, &c., 1742) show that the Wolf was always a scarce animal, and is now probably extinct. The Wild Boar was formerly common, and much hunted: and the earliest historians mention Porcupines (*fig. 303.*) or Spined Pigs (*porci spinosi, armatidi spine*), as being wild in the forests of Etna: that this animal should not have been originally a native of Europe appears, therefore, highly improbable. Fazello, one of the earliest Sicilian writers, asserts that Fallow Deer (*Dama*) were found wild in abundance on the lofty mountainous chain of the Madonia (*olim* Nebrodes), and on that of Dinamare (*olim* Neptuni). From the latter, owing to its vicinity to Messina, both deer and forests have long since disappeared. We do not believe, indeed, that this noble animal is any longer wild in this island; but large herds are stated to exist in the woods of Mimiano, belonging to the Prince of Paterno and the Duke de Montalto, where they are preserved. The same authors mention the Stag as being particularly numerous, both on the sides of Etna and in the forests of the Nebrodes. Upon these latter mountains were also found numbers of Wild Goats, whose teeth were tinged with a golden hue, probably originating from the nature of some particular plant there abundant. Hares and Rabbits are now almost the only native quadrupeds to be met with: the latter are

PORCUPINE

not common; and the former are stated to have been introduced in the island by Anassila, tyrant of Reggio. (*Mong., Sic. Rec.*, vol. i. p. 283.)

2623. *Among the birds of Sicily* must be reckoned many species common to the opposite shores of Africa; these are principally of the wading tribe. The swampy lakes and inac-

cessible morasses of Leontini and Syracuse afford shelter to vast flocks of waterfowl, which arrive during the spring and autumnal migration. The *malaria*, a most virulent and fatal species of ague, engendered by these low lands, renders them almost uninhabitable during the greater part of the year, and is a sure protection to the birds themselves. The immense flocks of quails (*fig. 304.*) which pass by the way of Sicily to the northern parts of Italy,

QUAIL.

among the common migratory visitors, and give to the ornithology of Sicily an interest which it would not otherwise possess.

2624. *The insects of Sicily* are more numerous than might be expected from the bare and unsheltered nature of its surface. The character of its entomology is decidedly more allied to that of northern Africa than of central Europe. All those genera which delight in a hot, sandy soil are particularly numerous: as *Scarabæus* (*MacLeay*) *Trox*, *Pimelia*, *Scarites*, *Gryllus*, *Sphex*, *Amphicoma*, *Bembex*, *Chrysis*, *Osmia*, &c. Sicily is very rich in hymenopterous insects; and of the genus *Anthrax*, or Sand Flies, we discovered near thirty species in the vicinity of Messina alone.

2625. *The Butterflies* (*Papilionidæ*) are numerous, and comprise the most elegant species known in Europe. *Podalirius europæus* Sw., *Gonepteryx Cleopatra*, *Eurymus hyale* Sw. (*fig. 305.*), *P. Daplidice*, *A. Lathonia*, &c. are common. Africa imparts to Sicily one of her most superb and imposing butterflies in the rare *P. Jasius*, *Jasia europæa* Sw., which we have occasionally captured near Messina.

EURYMUS HYALE.

2626. *Flights of devastating Locusts*, unknown to the other parts of Europe, have occasionally afflicted this fruitful island. The earliest upon record is mentioned by Fazello, who says that (about the 15th of May, 1355) the heavens were darkened by vast clouds of locusts coming from Africa; that they spread over the island, and began to make all verdure disappear; but that a sudden change of wind taking place, as if by miracle, they departed in dense squadrons, and were driven into the Ionian Sea, where their bodies, being cast upon the shore, caused such putrefaction, that a grievous plague ensued.

2627. *More recent flights of locusts* appeared in 1637, and in the four years following 1656; also in 1687, 1688, and 1689. But the most destructive appears to have been that of 1708. These terrific insects, as Mongitore relates, first landed at Sicily; from whence, spreading themselves in vast armies over the whole island, they caused devastation and ruin, during the five following years. In modern times the island has happily been spared from this scourge.

2628. *Malta and Gozo.* *The animals of Malta and Gozo*, as may be expected, are few; yet, as we can write from personal knowledge, a few notes on the zoology of these detached islands, should not be neglected. Of native wild quadrupeds, we believe, there are none larger than a rabbit. During the spring and autumnal migration, Quails, for a short time, are in great abundance, and the beautiful Merops, the Golden Oriole (*fig. 306.*), and the

GOLDEN ORIOLE.

elegant crested Hoopoe, are sometimes to be met with in the market. The large bird called the Maltese Vulture must be expunged from our systems, being no other than the Alpine Vulture (*Cathartes percnopterus* Tem.) in a young state: it was probably a straggler from Africa, or the lofty mountains of Sicily; for these birds could find no permanent habitation or shelter in the flat cultivated table-land of Malta. The little island of Lampidosa is remarkable for being the habitual residence of the most elegant of European birds, and one, also, which has never been recorded as such: this is the Coronated Crane, or L'Oiseau Royal of the French (*Ardea pavonia* Lin.): several of these were captured in 1812, at Lampidosa, and brought to Malta alive. To this solitary and nearly uninhabited island the Flamingo and many other wading birds of Africa occasionally resort.

2629. *The fish* are in great variety, and at all times afford a plentiful supply for the table : yet the species are, for the most part, similar to those of Sicily. The inhabitants, being catholics, consume great quantities of shell-fish. The oyster is, indeed, unknown ; but the harbour and coasts round La Valetta supply abundance of *Murex trunculus* (fig. 307. a),

a, MUREX TRUNCULUS. b, MUREX BRANDANUS.
c, LITHODOMUS DACTYLUS.

M. brandanus (b), both much better tasted than our whelks. Immense quantities of the *Lithodomus dactylus*, or Boring Muscle (c), are annually consumed. Indeed, the whole island, from its geological nature, is but a vast *nidus* for this singular shell-fish, which perforates the soft rock, below the water, with the smoothness and regularity of an auger. In the still inlets and recesses of the creeks and harbours, may be found a great variety of radiated Mollusca, which, from the pellucid nature of the water, may be clearly discerned at a depth of eight or even ten feet.

2630. *The domesticated animals*, and the uses they are applied to, excite the attention of Englishmen on first visiting the island. The oxen are large, and have enormous horns, being the same breed as that of Sicily : all the heavy draught work is performed by them, both in town and country. The horses are mostly imported from Barbary ; and the breed of asses is not inferior to that of Spain. The mule is universally employed for lighter purposes ; and the old Maltese families still adhere to the ancient custom of using them in carriages, in preference to horses. Cows are rarely seen, the artificial soil being too valuable for agriculture ; but goats abound, as they thrive on the scanty herbage of the rocks, and supply all the milk and fresh butter which is required. Sheep may be considered a curiosity both in Sicily and Malta ; for mutton is rarely seen, even at the highest tables. The Maltese dog is nearly extinct, the common breed being more like the pointer, and half spaniel. Rats are so large and numerous, that, during the famous siege of La Valetta, they became delicious food to the starving Maltese, and sold at a high price.

SECT. III. *Historical Geography.*

2631. *The history of Italy* is unrivalled in the magnitude of its events, and their influence upon the general destinies of the world. Our limits and plan can allow only a very hasty sketch of the mighty revolutions of which this country has been the centre.

2632. *Of the early nations of Italy but little is known.* The Etruscans, by the works of art handed down by them, especially in the form of terracottas, appear to have been a civilised as well as a powerful and free people. The south, colonised from Greece, and even denominated Magna Græcia, was the seat of the most celebrated of the early schools of science : Pythagoras taught at Crotona ; and the Samnites, by their gallant resistance to Pyrrhus, and afterwards to the Romans, established their name as a military nation.

2633. *Rome sprung up amid these nations* rather as a band of refugees than as a regular state. The Romans then subjected, one after another, first the neighbouring tribes, then the whole of Italy ; and afterwards crossed the seas, to conquer all the known world. Among their high and energetic virtues and daring exploits, they retained still a character of rudeness : and the first influence of their conquests was to extinguish in the subject nations the degree of civilisation they already possessed. Etruria lost her early arts, and Carthage that immense commerce which embraced all the known seas of the globe. But as the hardy captains of Rome penetrated to the cities of Greece, and saw the matchless works of architecture and sculpture with which they were embellished, their rugged pride was softened, and they were smitten with the love of these beautiful arts. The orators of the Forum sought next to transfer the splendid powers of eloquence which had given dignity and splendour to Athens. At last Cicero undertook to transplant the Grecian philosophy. Unfortunately, at the same time, the chiefs who returned laden with the spoils of so many nations introduced an unbounded luxury, which vitiated altogether the truth and simplicity of ancient manners.

2634. *The empire of Rome*, the most extensive and opulent ever established, was, after dreadful convulsions, erected on the mighty ruins of the senate and the republic ; and the world became as it were the inheritance of a single man. On such a trying and perilous eminence, examples were presented of the most unbounded cruelty and dissoluteness ; yet also of the most wise and enlightened humanity. During the Augustan age, poetry and all the fine arts were patronised and cultivated with ardour after the Grecian model, and carried almost to an equal pitch of perfection. The oppressive sway, however, of successive tyrants, and the brutal licence of the prætorian guards, soon left little more than that barbarous voluptuousness which generally characterises a purely despotic government.

2635. *The decline of the Roman empire* was attended with calamities to Italy and to man-

kind, still more dreadful than those with which its rise had been attended. The barbarians of the north and east of Europe, allured by the reported wealth and weakness of the empire, pressed continually closer on its frontier. They were kept in check for some time by the Danube and the Alps, and by the remaining strength of the legions. At length they burst all these barriers, and ravaged the beautiful plains of Italy. The transference to the East of the seat of empire left this portion with an unequal share of the common defence. Rome itself, the imperial capital of the world, became the prey of barbarians; it was successively sacked by the Goths under Alaric, and the Vandals under Genseric.

2636. *The sceptre was snatched from the feeble hands of Augustulus*, and the western empire was extinguished. The kingdom felt a gleam of reviving prosperity under Theodoric the Ostrogoth and Theodosius the Great, but was soon overwhelmed by fresh swarms of barbarians, among whom the Lombards were the most conspicuous, and have given their name to the northern plain watered by the Po.

2637. *The empire of Charlemagne* suspended the troubles of Italy, but formed the commencement of that long series of ultramontane dominion, to which she has been subjected. When the members of that empire, France and Germany, separated from each other, Italy fell to the lot of Germany, which retained the imperial name and dignity, but ever afterwards found this country a turbulent and precarious appanage.

2638. *The spiritual authority of the Popes* formed a new species of empire, which seemed to invest Rome with a grandeur almost equal to that which she had displayed under the Cæsars. After a gradual progress, it rose, under Gregory VII., to such a height, that Henry IV., the most able and powerful prince of his time, was fain to present himself bare-headed and barefooted, and on his knees implore forgiveness for having ventured to dispute the spiritual authority. From this time these proud pontiffs not only claimed the right of disposing absolutely, throughout the Christian world, of all the officers and ministers of religion, and of exacting from it the regular tribute of "Peter's pence," but even of excommunicating and deposing the greatest kings. As the emperors, however, did not tamely submit to these usurpations from a power which they considered in a temporal sense as subordinate, a series of struggles ensued, which scandalised the church and distracted Europe.

2639. *The rise of the commercial republics*, Venice, Genoa, and Florence, formed a brilliant era for Italy, enabling her almost to equal the most splendid ages of antiquity. Their navies, both for war and commerce, covered the seas, and set bounds to the all-grasping ambition of the Ottoman, which threatened to overwhelm the whole western world. By degrees, also, the lamp of learning, which had shed for ages only a dim light over Europe, broke forth here into full effulgence. The remains of Greek literature were conveyed over by the learned men who fled before the sword of the Turks; the writings of the ancients were drawn from the depth of convents, and eagerly studied and circulated. What was of more consequence, a race of enlightened princes and nobles arose, who sought glory in patronising knowledge, while a general taste for it was diffused among a wealthy and refined community. The arts of painting, architecture, and music, on which the wealth of the noble citizens was lavishly expended, rose to an eminence equalling, perhaps, that of the ancients, and surpassing that of any other modern nation.

2640. *The decline and degradation of Italy* rapidly ensued after this brilliant era. Her great republics lost the liberty which had rendered them so flourishing; their arts and commerce were transferred to the northern maritime states. The great monarchical powers, after long struggles, reduced her territory to a state either of subjection or vassalage; while they continued at the same time to make her soil one of the great theatres of contention. Italy had reason more and more to deplore "her fatal gift of beauty," which became so fruitful "a source of present woes and past;" she was branded even with the appellation of "slave of slaves." Rome herself lost her spiritual greatness, which was withered even in catholic countries by the progress of reformation. The late revolutions of Europe, though they produced in Italy many eventful scenes, can scarcely be considered as forming an era in her destiny. They had only the effect of sealing her degradation, by extinguishing what remained of the independence of her once great republics, Venice and Genoa. The Italians are said to regret the lost name of the kingdom of Italy given by Bonaparte to the northern districts, though accompanied not with any portion of political freedom, but with some beneficial regulations of law and police. In general a great body of the Italian people manifest a deep sense of the fallen state of their country, and an eager desire to seize any favourable occasion to revive its ancient glories; but as yet the iron hand of Austrian military power has crushed in the bud every tendency of this nature.

SECT. IV. *Political Geography.*

2641. *The political state of Italy* presents nothing on which the wellwishers of that country can look with much satisfaction. It is divided among five potentates: the Emperor of Austria, who holds Lombardy and Venice, to which may be added Parma and Pla-

centia, the appanage of Maria-Louisa; the King of Sardinia, who has Piedmont, Savoy, and Genoa; the Grand Duke of Tuscany; the Pope, temporal ruler of the States of the Church; the King of Naples and Sicily. The constitutions of all these sovereignties possess an unhappy simplicity; the will of the ruler operating unchecked by any legal or constitutional limit. Neither the great civic nobles of the commercial states nor the feudal nobility of the country have any effective influence in the administration. They only exercise, by their immense fortunes, a pernicious influence in checking the operations of police, throwing the public burdens on the industrious classes, and depriving them of the just protection of the laws. The police over all Lower Italy is in the most imperfect state. Bands of almost licensed robbers occupy the mountain districts, and make frequent inroads into the plain; thus rendering a great part of their territory unfit for the residence of the cultivator.

2642. *The only tie between the separate governments of which Italy is composed* consists in the paramount influence of Austria; the power of all others which sets itself in the most fixed opposition to political reform. The Emperor of Austria has his brother Grand Duke of Tuscany, his father-in-law King of Naples, one of his daughters Duchess of Parma and Placentia, and the family of Sardinia bound to him by close ties of consanguinity. What is of more consequence, his troops also are in a position to overcome any one of them which should adopt measures contrary to the views of this high potentate. Being otherwise unconnected with each other, and none of them powers of the first rank, they present no political features which may not be exhibited in describing the local divisions of Italy.

SECT. V. *Productive Industry.*

2643. *The productive wealth of Italy* has suffered greatly in the decline of her other sources of prosperity. Yet such is the felicity of her soil and climate, and so considerable are the remains of her industry, that the entire produce of her land and labour is still ample and valuable.

2644. *Agriculture*, as Smith has observed, is one of those plants which take such deep root, that only extreme tyranny and misrule, and scarcely even these, can eradicate them. Italy is now dependent upon other countries for the superb fabrics with which she formerly supplied them; her ships no longer cover the Mediterranean; her merchants, who were once her nobles and her princes, retain only the shadow of mighty names. But the plains of the Po, the Arno, and the Garigliano are still cultivated like gardens; and the agricultural produce, after supplying a very dense population, affords a large surplus for export.

2645. *Culture in Italy* is conducted by a class of farmers to whom we have nothing analogous in our part of the world. The stock is furnished half by the landlord, and half by the tenant; and the produce is equally divided between them. The lease is only from year to year; but a tenant who pays his rent, and does not give any serious offence, is never removed: Mr. Forsyth considers the productiveness as being invariably in proportion to the smallness of the property; a result the reverse of what obtains in this country; but the cause probably is, that, under a system of management where the landlord co-operates, the part of those holding large estates committed to stewards and substitutes is commonly very ill done, and their avidity for money shows itself only in extortion. The property of the great ecclesiastical nobles of Rome has thus been converted into a pestilential desert. In Lombardy and Tuscany, however, the mercantile intelligence of the opulent owners has been employed in important rural improvements; the wealth of these districts is chiefly due to the astonishing works constructed at an early period for the purpose of irrigation. Several of them were executed at periods prior to the era of authentic record; others in the twelfth, thirteenth, and fourteenth centuries. The aqueducts, sluices, and other works connected with them, are still the admiration of engineers. They are now so divided and subdivided, as to convey the means of irrigation almost into every field; and in this southern clime, where nothing almost but water is wanted, the increase of fertility is almost incredible. The produce is sometimes more than tripled; and grass may be mown three, four, and five times in the year. The property of water, thus the grand instrument of cultivation, is fixed and distributed by the minutest regulations. Every spring newly discovered belongs to the proprietor of the ground, and is by him immediately converted into a little canal. The enclosures are small, and surrounded, for the sake of shade, by poplars and mulberry trees, which give the country a rich wooded appearance. The farm-steadings are kept very neat and clean. In the Tuscan vale of the Arno, the irrigating system is practised on a different and still more elaborate method. The steep slopes of the Apennine, from which the waters poured down only in irregular torrents, seemed incompatible with such a process. Recourse was had to the terrace system, which, though not uncommon in Asia, is in Europe almost exclusively Italian. The processes by which level spots have been formed on the sides of the steepest mountains, naked rocks covered with earth, torrents confined within walls, and guided in little canals along almost every field, could only have been effected by the

Florentine merchants in their greatest prosperity. The people of the present age with difficulty support the heavy expenses of repairing and keeping up these most useful works. The cultivation in Naples does not require such elaborate processes. All that is there wanted is shade, which is procured by dividing the country into very small fields of less than an acre, and planting each side with high trees, round which vines are trained. The land is almost entirely tilled with the spade; but the poor cultivator is obliged to give two thirds, instead of one half, to the proprietor. The Neapolitan Apennine is not cultivated with the same elaborate care as the Tuscan; but nature profusely covers it with the chestnut and the olive. An entirely different system prevails in the great *maremmas* or plains along the sea-coast, which, from some cause not fully ascertained, are filled at a certain season with air so pestilential, that human beings cannot remain for any length of time without the loss of health, and even of life. These wide plains, surrounding the greatest cities of Italy, present a scene of the most dreary desolation, and are covered merely with wandering herds, watched by a few mounted shepherds, who, however habituated to the climate, labour under constant debility. Once in about six years each spot is brought under the plough, for which purpose numerous bodies of labourers are brought from Rome and Sienna; and sometimes a hundred ploughs are employed at once, in order to get over as soon as possible this dangerous operation. The farmers are few in number, not more than eighty in the whole Roman state. They reside constantly in the cities, have large capitals, and long leases; and some of them have live stock worth 16,000*l*.

2646. *The objects of agriculture in Italy* are numerous and important. They include grain of all the most valuable descriptions. The wheat of Sicily, and still more of Sardinia, is reckoned the finest in Europe. Maize is a prevalent grain, chiefly for the food of the lower orders; and even rice is raised with success, and to a considerable extent, in the inundated tracts of Lombardy. Silk is an universal staple, and of very fine quality. The export of it, in a raw or thrown state, since the decline of internal manufactures, has been the main basis of Italian commerce: it is sent to all the manufacturing countries, and shares with that of China and Bengal the market of Britain. The vine finds almost every where a favourable situation, and is cultivated; but the juice no longer preserves the fame of the ancient Falernian. It is in general too sweet, and too imperfectly fermented, to admit of exportation. Mr. Eustace endeavours to turn this circumstance to the honour of the national character, conceiving that the sober Italian, who drinks to quench thirst, has no motive to study the preparation of a delicate wine. The wines of Naples and Sicily are the best, and are sometimes seen at the tables of the great in foreign countries. The Muscatel and other Sicilian wines are so extremely luscious, that only one or two glasses can be taken at a time. That island, however, has another kind, the Marsala, often sent to America and the West Indies, where it passes for Madeira. The olive grows in very great luxuriance in Naples, on the eastern slope of the Apennines; and the oil made from it is more highly esteemed than any other, at least for use in the finer woollen manufactures, whence it finds in England a steady demand, under the name of Gallipoli. Cattle are not particularly numerous; but many of them, from their qualities, are singularly valuable. Pre-eminent among these are the cows fed in the pastures of the Parmesan, and the country around Lodi, which produce the cheese considered superior in richness and flavour to any other in the world. The cattle are of the Hungarian breed, crossed with the Swiss; they are fed in the stall upon mown grass; and numbers of the small proprietors keep a dairy in common, that they may conduct the process on a large scale. The cattle on the Apennines are of a small grey kind, which Mrs. Graham praises as the most beautiful of their species; but they give little milk, and after being employed in labour are driven down to the Maremma to be fattened for the city markets. The sheep abound in all the mountainous districts, and their wool is generally esteemed. That of the Venetian hills has, by crossing with the merino, been rendered almost perfect; and that of the mountains of Rome and Naples, though not so fine, is valued for the equality of its texture. A great part is black, and woven undyed, for the clothing of the galley slaves and of the friars. Goats are reared in great numbers amid the Apennine cliffs; and their flesh and milk is the animal food chiefly used by the cultivators, with the addition, however, of fresh pork. Hogs are reared also in great perfection; they are not pent up, and fed on refuse, but wander at large through the woods, where they feed on nuts, mast, and roots; and become even somewhat intelligent and sprightly animals. The hams and bacon thus produced are considered at Rome as a great luxury. The fruits of Italy are various and delicious, but none are of such value as the chestnuts, which in the upper regions constitute the food of a numerous body of mountaineers, who even dry and convert them into bread. The Apennine timber, consisting chiefly of oak and chestnut, is little used except for barrels. The saline plants of Sicily yield a barilla which rivals that of Spain. Among partial objects we may mention cotton in the southern provinces of Naples, which was produced in 1812, to the amount of 60,000 bales, and the hemp of Bologna, which is of peculiar excellence. The Neapolitan manna, which exudes from a species of ash, is made a royal monopoly.

2647. *The manufactures in Italy*, once remarkable for their elegance and variety, are now

every where in a state of decay, and present only specimens on a small scale of what formerly existed. The great and opulent citizens, after the military revolutions which deprived them of influence and security, seem every where to have retired to the country, and invested their capital in land. Silk was formerly the grand staple, particularly in the form of velvets and damasks, richly adorned with gold and silver embroidery. This manufacture still exists in most of the great cities, though on a reduced scale. The Venetian States, in 1795, had only 2701 silk weavers, and 1163 gold and silver spinners. In 1802, the number of weavers in Turin had been reduced from 1400 to 500. The Lombard peasantry, however, still carry on the throwing of silk upon their farms, and it is exported in the shape of organzine for the use of the foreign manufacturer. The woollen manufactures of Florence were once immense, giving employment to 30,000 persons; but they are now both few and coarse. Linen is considerable, and is often combined with cotton, which flourishes tolerably in the southern provinces of Naples, where the muslins of Tarento enjoy a good deal of reputation. Glass, in brilliant and curious forms, was once a celebrated and admired article; and there are still made at Venice, on the island of Murano, mirrors, glass beads, and tubes; at Florence, the flasks bearing the name of that city. It seems doubtful if the art that produced the ancient earthenware of Etruria still exist. In the Florentine and Roman States are made, without the use of the wheel, numerous jars of red earthenware for holding oil; probably on a very antique model. The works of Doccia, near Florence, produce goods resembling those of Staffordshire. The only fine porcelain of Italy is that made at Naples, which may vie with any in Europe. The potteries at Terramo, in the Abruzzo, are also very extensive. Some curious works, inlaid agate tables, cameos, mosaics, &c. which elsewhere rank with the fine arts, are carried to such an extent, at Florence and Rome, as to be articles of trade. The paper of Italy had formerly a high reputation; and that of Belluno, and some parts of Tuscany, is still in repute. Extremely fine soap is made generally throughout Italy, but more particularly in Sicily. The Tuscan manufacture of straw hats affords valuable employment to country girls, and yields a produce of about 150,000*l.* a year.

2648. *Minerals*, especially metals, are deficient to a degree remarkable for a country so very mountainous. The Alps, which are so rich on the side of Germany, produce on that of Italy only iron in the districts of Brescia and Bergamo, and copper in that of Belluno. The Brescian iron has been worked with considerable diligence, being formed into the steel celebrated under the name of Brescian, and into various descriptions of hardware, which, however, have shared the general decline of Italian industry. Notwithstanding the boasts of some native writers, no mines of importance seem to exist in any part of the Apennines or of the rest of Italy, except in the island of Elba, long celebrated for its fine iron. The cliffs of this great calcareous chain, however, produce valuable stone, and particularly several species of beautiful marble, among which that of Carrara is conspicuous; nor are there wanting agates and other ornamental stones. The sulphur of Sicily is an article of importance.

2649. *Commerce of Italy*. This, though not nearly so great as it might be were her energies developed, is, notwithstanding, of very considerable importance and value. The principal articles of export are, raw and thrown silk, silk manufactures, and olive oil; the articles next in importance are, corn, wine, cheese; raisins, almonds, and oranges; brimstone, barilla, liquorice, bark, shumac, straw hats and straw platting, marble, hemp, rags, &c. The imports consist principally of cotton goods, yarn, and wool; all sorts of colonial produce; timber and iron from the north of Europe; dried and pickled cod, pilchards, &c. The commerce between England and Italy is very extensive. With the exception, indeed, of the United States, the East Indies, and Germany, our exports to the Italian ports are greater than to those of any other foreign country. Cotton stuffs and cotton twist form by far the most important of all the articles we send to Italy; their real value in 1831 having amounted to no less than 1,500,000*l.* The real value of our exports of refined sugar to Italy during the same year exceeded 500,000*l.* We also supply her with quantities of hardware and cutlery, woollens, linens, dried fish, &c. The grand total of the real or declared value of our exports to Italy in 1831 amounted to 2,490,000*l.* It should, however, be observed, that a certain proportion of these exports go to Switzerland, Austria, and Hungary; but we have no means of determining the exact quantity that is thus disposed of. During the same year we imported from Italy 2,557,000 gallons olive oil; 526,000 lbs. of raw silk, besides a large quantity that came by way of France; 253,000 quarters of wheat; 287,000 gallons of wine; 23,867 cwt. of barilla; 264,000 cwt. of brimstone; 127,000 cwt. of shumac; 76,547 straw bonnets, &c. The foreign trade of Italy is principally centred in the ports of Leghorn, Genoa, Trieste, Naples, and Palermo. The first two are very important entrepôts; and are usually supplied with large stocks of the most important products of the Black Sea and the Levant. For further details as to the commerce of Italy, the reader is referred to M'Culloch's *Dictionary*, second edition, articles Genoa, Leghorn, Naples, Palermo, and Trieste.

2650. *Fishing* is a pursuit for which the extensive coasts of Italy, as well as its lakes and rivers, furnish ample scope, as they abound with fish of the most excellent quality. It is carried on with sufficient diligence for immediate consumption, but not so as either to furnish

carried on with sufficient diligence for immediate consumption, but not so as either to furnish objects of trade, or to dispense with a large importation. Anchovies, however, are shipped in large quantities from Sicily for Leghorn; and it seems to be from some defect in the mode of cure that they do not equal the Gorgona anchovies. On the western coast of the same island is a considerable coral fishery. Amber, as a marine production, may also be mentioned as found more abundantly on the Sicilian than on any other coast. The tunny fishery of Sardinia is the most extensive in the Mediterranean.

2651. *The canals*, constructed during the period of the glory of Italy, are very numerous and valuable. The plain of Lombardy is intersected by twelve on a large scale, connected by innumerable minor channels. But though many of these are navigable, their primary object has been to communicate to the country on both banks of the Po its unrivalled fertility. This is still more decidedly the case in the Florentine canals, which are merely broad ditches cut along the terraced sides of the mountains. The only canals of the south appear to be those which have been formed at different times with a view to the draining of the Pontine marshes. Commercial canals do not seem to have yet entered into the system of Italian economy.

2652. *The roads of Italy* were carried to the highest perfection under the ancient Roman empire and republic. From Rome, as a centre, five great ways branched off to the different frontiers. All obstacles were removed, rocks levelled, hollows arched over, in order to form routes the most direct, level, and commodious. They were constructed in a peculiar manner with large blocks of stone wedged together so as almost to resemble a flat surface of rock; and such is the durability thus produced, that several large portions remain, after the lapse of two thousand years, in as entire a state as at their first formation. The lines of these great roads still continue, and are kept by the existing governments in very tolerable condition; so that travelling in Italy is obstructed only by the occasional inundations of the rivers, and the still more perilous assaults of banditti, who occupy many of the Apennine recesses.

SECT. VI. *Civil and Social State.*

2653. *The national character and the state of society in Italy* are marked by prominent and striking features. The people, in some respects, are perhaps the most polished and refined of any in the world. While the German and many English nobles placed their enjoyment in hunting and the pleasures of the table, music, painting, poetry, and assemblies for conversation formed the delight of the Italians. The one spends much of his fortune in keeping a splendid table, stud, and pack of hounds; the other in building palaces, and adorning them with masterpieces of painting and sculpture. The French are, perhaps, still more gay and social; but their gaiety is more of a noisy, empty, and animal kind; while the Italian derives his delight from objects of taste, and feels them with deeper sensibility. The nobles of this country were from the first civic; and all their habits have continued to be those of a city. What they call the chase has no resemblance to the bold adventurous field-sports of England, but consists merely in driving a number of animals into an enclosed place, and shooting them at their ease. No pains are bestowed on the improvement of their estates, which are managed according to a mechanical routine, under the care of stewards, who often embezzle a great part of the produce. Being excluded also from all concern in public affairs, and from the administration of the state, they have become estranged from habits of manly and energetic exertion. They pass their lives in a listless and lounging apathy, making it their sole object to while away the hour in the most easy and agreeable manner. Their day is spent in a regular routine of attendance on mass, on their lady, on the theatre, the Casino, and the Corso. As the title and rank of a noble descends to all his posterity, the great increase in their number, by reducing them to a miserable and proud poverty, tends still more to degrade them in the public eye. Certain remains of mercantile habits are offensive to English observers. Ostentatious magnificence is combined with sordid economy; the most superb equipages and apartments are let out to foreigners, who are not even quite sure of honest dealing. Attached to many of the Florentine palaces is a little shop, where wine is retailed in the smallest quantities. But the deepest reproach of Italian manners seems to be the established system of *cicisbeism*, by which every married lady must have her lover or *cavaliere servente*, who imposes on himself the duty, wherever she is or goes, to dangle after her as her devoted slave. This connection is said to be not decidedly, or at least certainly, criminal, as our manners would lead us to suppose; but rather to form an *état* into which it is necessary to enter, on pain of expulsion from the fashionable circles, and which is continued according to a routine of almost mechanical observance; the gallant speaking not of the mistress whom he loves, but of her whom he serves. It is obvious, however, that it must, at the very least, imply the sacrifice of all that is happy or respectable in domestic life, attended as it is with an anathema against the married pair, if they show the slightest symptoms of respect or regard for each other. Still charity and humanity appear conspicuous virtues in these nobles.

The *misericordia*, an institution diffused throughout Tuscany, consists in Florence of four hundred persons, many of high rank, who devote themselves to personal attendance on the sick, superintending the hospitals, distributing food to the patients, and watching the manner in which they are treated. These duties, indeed, they perform under the disguise of long black vestments, which cover and conceal the face. There is another society for searching out and relieving the poor who have seen better days, and are ashamed to beg: but in Mr. Forsyth's time their zeal had so far relaxed, that they bestowed alms only upon application; and Mr. Williams considers their original object as wholly lost sight of. The charitable institutions of Naples, Rome, Milan, and Genoa, appear also to be most extensive; and the bounty bestowed, especially at the convents, is considered as one of the chief causes of the idleness and mendicity which prevails in the great cities. Temperance must be admitted as another virtue of the Italians. Notwithstanding the abundance and cheapness of wine, intoxication is scarcely known, even among the lowest ranks. English visitors complain that, amid the profusion of other forms of courtesy, little food or drink is vouchsafed to them, even by the most opulent. A dinner is an event of the rarest occurrence; and the amusements of the evening are only those of intellect or society, without any refreshment whatever. The accompaniment of real politeness and civility, however, shows that this proceeds not from want of hospitable feelings, but of that importance which is attached to good cheer by the English nation.

2654. *The lower ranks form the mass of the Italian population*, with scarcely any intervening class between them and the nobles. They share, in some degree, the refined tastes and manners of the higher ranks. The common shopkeepers of Florence and Rome possess a taste in the fine arts, and sometimes even in poetry, which is unknown in the most polished circles beyond the Alps. They delight also in conversation, which they support with peculiar animation, and with gesticulations the most varied and expressive of any European people. The peasantry are, on the whole, a poor, quiet, contented orderly race; spending, not very wisely, all their little savings in finery for their wives and daughters. But the populace of the great towns display a character peculiarly idle, tumultuary, and unlicensed. They seem to combine the characters of citizens, beggars, and bandits. The *lazzaroni* of Naples, in particular, form a numerous body, who exist almost wholly out of the pale of regular society. The climate enables them to live without houses, — almost without clothes, and with only a daily handful of *maccaroni*. Having obtained this by theft, by begging, or some little occasional work, they abandon themselves to luxurious indolence, or the indulgence of wayward humours. They are a set of wild merry rogues, with all the rude energy of savages, full of humour, address, ready argument, and quick repartee. In political convulsions they have made very signal displays of energy, usually in defence of the reigning family, to whom they are strongly attached. The practice of assassination, whether for hire or on the impulse of passion, which was long peculiarly Italian, is said to have been considerably reduced by the French. They deprived the sanctuaries of their right to protect the assassin; and that right has not since been restored to them. Another too numerous class are the bandits, who, established in the recesses of the Apennines, form a sort of separate people, and carry on their vocation on a great and regular scale. The strength of their line of mountain positions, which runs close and parallel to that of the high road through Italy, affords them opportunities of which they know well how to profit. The road from Rome to Naples is their favourite haunt, and even when guarded by piquets of soldiers at the distance of every mile, it cannot always be travelled with safety. They carry on their trade in a systematic manner, and not without some adherence to the principle of honour when it has once been pledged. Their grand aim is to carry off some person of distinction, and then to exact a ransom proportioned to his means and dignity. The French and even the German troops stationed in Naples rooted out some of these dens of banditti; but, under the supine indolence of the Neapolitan government, they are again recruiting their strength.

2655. *Religion* still forms a prominent feature in Italy, the centre of that great spiritual dominion which for so many ages held unbounded sway over Europe. The pope, as spiritual head of the catholic church, maintains an establishment rather suited to his former supremacy, than to the limited and almost nominal jurisdiction which he now exercises. The great council of the church consists of the college of cardinals, who, according to the regular establishment, amount to seventy: they are chosen by the pope, and on their part they elect him out of their body. Every fortnight they are assembled in a consistory, to deliberate on the general affairs of the church. Particular departments are also administered by congregations, which have not the signification which we attach to them, but signify public boards. There is a congregation *de propagandâ fide*, for missions to foreign parts and the conversion of heretics; the congregation of the *index*, for making up the list of prohibited books. The Jesuits, since their re-establishment in 1817, have also their headquarters at Rome, where their *general* resides. The inquisition, now much mitigated in its rigour, forms one of these congregations. There are thirty-eight archbishops in Italy; and the number of suffragans varies according to the pleasure of the pope. The clergy,

both secular and regular, were, prior to the Revolution, very numerous; and their possessions were immense, consisting chiefly in land. The tithes were not very severe, and in Tuscany had been altogether abolished. During the French revolutionary sway there was an extensive confiscation of ecclesiastical, and especially of conventual property; and though this has been partly restored, much still remains in the hands of the lay purchasers. It is said that not much benefit has thence accrued to the cultivators, who have merely found a new and often more rigid landlord. Another means of support to the church is from alms; and the two most powerful modern orders, the Dominicans and Franciscans, have expressly announced themselves as mendicant; but the spirit of the times renders this source of wealth much less productive than formerly.

2656. *The ceremonies of the Roman catholic church* are exhibited at Rome in all their imposing splendour. Mr. Eustace considers the pontifical service at St. Peter's, and the procession on Corpus Christi day, as, perhaps, the most magnificent spectacles that are exhibited in the universe. All the parade of dress, the blaze of light, and the pomp of music, are united in the magnificent hall of the Vatican, and the vast area of the church of St. Peter, to produce the most imposing and brilliant effect: one of the most striking scenes is said to be in St. Peter's, on the night of Good Friday, when the hundred lamps that burn over the tomb of the Apostle are at once extinguished, and in their stead a stupendous cross of light appears suspended from the dome: in one part of the ceremonies the Pope makes a show of washing the feet of pilgrims, while in another he bestows his benediction on the assembled multitude. These great days are preceded by periods of severe fasting, and followed by a carnival, or interval of almost unbounded licence. The gloom of the first period is described by Lady Morgan as enlivened by busy preparation in draping the churches, clothing altars, and forming festoons; also in preparing dresses, crowns, necklaces, and cradles for the Madonna and Child of the respective churches. Sometimes the Virgin blazes in pearls and diamonds; sometimes she can only get a tin crown, set off with gilt paper and glass beads. Mary, according to Mrs. Graham, is the goddess of Italy: even the robbers, who are generally devout, never go forth on a marauding expedition, without her image carefully tied round the neck; they consider it even as a spiritual benefit to be hanged, as they then get absolution immediately before they drop, and can commit no further sin. We can scarcely, however, believe, with Mrs. Graham, that it is customary with the Italians to commit capital offences with the sole view of securing their salvation. According to Mr. Matthews, there appears to be some good preaching in Rome: one friar he compares to Dr. Chalmers for vehemence and enthusiasm, though without the same rich variety of knowledge and illustration; but he employs himself very laudably in attacking the prevalent faults, and particularly that attachment to the outward forms of religion which is here so generally substituted for its essential duties.

2657. *In literature and science*, the world is deeply indebted to Italy; first for the classical works which she produced during her Augustan age; and then for the brilliant revival of literature, under her auspices, after a long night of ignorance. In the fifteenth and sixteenth centuries she could boast of Petrarch, Dante, Tasso, and Ariosto, as standing in the first class of poets; Guicciardini, Fra Paolo, Machiavel, unrivalled among the historians of their own and several succeeding ages; and Galileo as attaining the highest distinction in astronomy and physical science. Along with the political ascendancy of Italy, her literary greatness has suffered decay; the magnificent patronage of the Medici and the Estes was no longer extended to it; and the national enthusiasm, by which it had been fed, was depressed by slavery and adversity. Italy, however, has not ceased from time to time to produce distinguished works. The lyrics of Giridi, Chiabrera, Filicaja, have attracted admiration; and the drama, which had been wanting in its fortunate age, was brought forward in a very imposing manner by Alfieri and Monti. At the same time the political works of Filangieri, Beccaria, and Verri, have displayed highly enlightened views; and Spallanzani, Fontana, and others have acquired distinction in medical and physical science.

2658. *The literary collections of Italy* are of singular value: the library of the Vatican, if not the most extensive, is probably the most valuable, in Europe; the number of volumes (a simple fact, which might be easily ascertained,) has been left to conjecture, which fluctuates, according to Mr. Eustace, between 200,000 and 1,000,000: he advises to take the middle, which makes a very vague kind of estimate. The manuscripts, the most curious and valuable part, are reckoned by him at 50,000, but by Mr. Cadell only at 30,000. They comprise very early copies of the gospels, the classics, and writers of the middle age. The French extorted the surrender of 500, to be selected by themselves; but if (as reported by Lady Morgan) the choice was capriciously made by illiterate officers, it may not have materially reduced the value of the collection. The Ricciardi and Magliabecchi libraries, at Florence, and that of the Institute of Bologna, though secondary to the above, contain, however, a rich store of ancient manuscripts and early printed works, formed by the munificent princes who once reigned over these cities. The riches of that of Milan have been sufficiently proved by the learned researches of M. Angelo Mai, who has retraced the lost works of Cicero and other classic authors, erased in order to make way for monkish legends that have been written

above them. The library formed by the house of Este, at Modena, notwithstanding severe and repeated losses, possesses still considerable wealth. At Naples, the papyri, dug out from the ruins of Herculaneum, present still one of the greatest modern literary curiosities.

2659. *The fine arts in Italy* have attained a splendour quite unrivalled in any modern country, and have even flourished in that region as their chosen and peculiar soil. An aristocracy living in cities, and estranged from rural habits, naturally centered their pride and gratification in covering their country with this species of embellishment. The houses of the Medici and of Este, with the nobles and senate of Venice, vied with each other in raising such monuments.

2660. *Painting*, in the sixteenth century, and in the Roman and Florentine schools, reached a height of perfection unequalled, perhaps, even in ancient times. In all the qualities of form, design, and expression, which constitute the highest excellence of the art, no names can yet rival those of Michael Angelo and Raphael. A school nearly contemporaneous was formed at Venice, which, as to the beauty of colouring, stands unrivalled. It is remarkable that, ever since this early period, the art has been in a state of gradual decline. The school of Bologna, however, which immediately succeeded, attained to very great excellence, just below that of its predecessor. But, for more than a century, though Italy has had some showy and popular painters, there have been none who could establish any classic reputation: at present, notwithstanding the respectable names of Camuccini and Naldi, the general character of art is very secondary. An ingenious writer complains of the cold, glaring, hard style adopted by those who have the opportunity of studying the most masterly of the ancient works. Indeed, Mr. Williams suspects that the constant copying of these works, and often for the mere purpose of sale, deadens the invention of the Roman and Florentine painters.

2661. *The sculpture* of Italy, even during its happiest ages, did not equal that of the ancient schools; though Michael Angelo and Bandinelli, combining it with painting, produced some very splendid specimens. In the present age the genius of Canova has burst forth with a brilliancy which has enabled modern times in this art almost to rival antiquity. Thorwaldsen, also, though a Dane, having been completely formed and fixed at Rome, has generally been considered as Italian.

2662. *Engraving* is an art subsidiary to painting and sculpture, and naturally following in their train. Notwithstanding the interesting school formed by Raphael, and the valuable etchings by the Bolognese painters, Italy seems, in this department, to have long remained behind France and Flanders. This reproach has been removed in the present age, when the patronage afforded by an association of nobles has produced Volpato, Bettelini, Gandolfi, and above all Morghen, justly, perhaps, considered as the greatest engraver that ever existed. The talent of these artists also having been employed solely on the finest pieces of the early masters, has rendered their engravings of peculiar interest and value.

2663. *Architecture* is another art in which Italy has no modern rival. Though some of the northern nations may have erected more huge and more costly structures, none of them display the same high, pure, and classical taste. Besides Palladio and Bramante, who hold the foremost place among professed architects, Michael Angelo employed himself in designing several great edifices, which are stamped with all the grandeur of his genius. Hence, notwithstanding the astonishing magnificence of the architectural remains of ancient Rome, they are completely matched by St. Peter's, the Lateran, S. Maria Maggiore, and other modern churches.

2664. *The collections of art in Italy* are of a splendour surpassing even that which might be inferred from the great works produced by its artists. Of the masterpieces of the ancients which were either saved from the desolation of the Eastern empire, or dug up from the ruins of temples and palaces, by far the greater part were either found in Italy, or brought into it; and that country became the grand depository alike of ancient and modern art. Even at the time when French rapacity had stripped it of all its moveable treasures, the grand productions of Michael Angelo, Raphael, Caracci, and Titian, painted upon the walls of temples and palaces, remained immutably fixed. Italian pictures form still the brightest ornament of all the collections beyond the Alps; yet the multitudes which have been purchased out of Italy, seem scarcely missed amid the profusion of those which remain. Rome continues still the great *studio* of all the nations of Europe: no painter is considered fully accomplished until he has spent a year or two in that capital; and many from the most remote countries, enamoured of its beauties and advantages, make it their residence for life.

2665. *In music*, Italy has boasted a similar pre-eminence; and for a long time all the great composers in the high style of art, Pasiello, Cimarosa, and Salieri, were exclusively Italian. Of late, however, Germany has come forward as a powerful rival; Vienna especially has produced several composers of the first class. Yet Italy seems still to be regarded as the chief home of the musical art; thither all the students repair; and its vocal performers are considered over all Europe as superior to those of any other country.

2666. *The amusements of Italy* have been already touched upon, in estimating the character of a people, of whom so large a proportion live only for amusement. The arts now

enumerated; as brought to such perfection, furnish a great part of their daily recreation; to which they add a still more refined one, improvisatory poetry. In all the societies of Italy, there are bards who are ready to recite a crowd of verses, upon any subject proposed, on the spot; and many have been celebrated as of great excellence. We are not aware, however, that any of the productions of these improvisatori have obtained the notice of the world in general; and it seems on the whole to be rather a process for the display of quickness of fancy, than one by which works of superior merit can be produced.

2667. *The mansions of Italy* are celebrated for the splendour and art displayed both in their form and interior decoration. Those built by the nobility in Rome, Florence, Genoa, and Venice, are usually dignified with the name of palaces; and their classic exterior, spacious apartments, and the works of painting and sculpture with which they are adorned, render them often more interesting to the spectator than those of the greatest monarchs beyond the Alps. They are maintained, however, rather for show than use; all the finest

TUSCAN COTTAGE.

apartments being employed as galleries of exhibition, while those in which the family reside are of small dimension, in the upper stories, and destitute of many of the comforts which, to an English gentleman, appear indispensable: in short, to him they appear little better than garrets. The taste for architectural beauty descends even to the lower ranks. The houses of the little farmers in Tuscany and Lombardy are adorned with porticoes and colonnades, and often display a classic aspect (*fig. 308.*).

2668. *The dress of the Italians* does not seem to have any features peculiar or strictly national. Among the upper ranks, French fashions prevail; many of those in the country, and especially of the hilly districts, display a picturesque variety, which, being not unaccompanied with taste, produces often a very pleasing effect (*fig. 309.*).

ITALIAN COSTUME.

2669. *In the food of the Italians*, who are generally very temperate, we know not any very characteristic article, except maccaroni. In the rest of Europe it has not been generally adopted as an article of diet, but it is presented as a delicacy at the tables of the opulent.

SECT. VII. Local Geography.

2670. *The local divisions of Italy* are more than usually prominent; for though the country is united by name, by a common language, and by a strong national feeling, it has yet been partitioned into a number of states, politically independent of each other. The numerous little republics, indeed, which once made so brilliant a figure, and disputed for supremacy, have, in the late convulsions, lost the feeble remains of their existence, and merged into the great states. Italy is thus divided into five great portions: 1. The Ecclesiastical States; 2. Tuscany; 3. Lombardy, or the Austrian States; 4. The States of the King of Sardinia; 5. Naples and Sicily.

SUBSECT. 1. Ecclesiastical States.

2671. *The Ecclesiastical States* have lost that paramount importance which they once possessed, and are the least flourishing and powerful of all the divisions of Italy. Nevertheless, as they contain Rome, with all its stupendous monuments, and were the central theatre of all the ancient grandeur of Italy, they still excite an interest superior to that of any other of these

celebrated regions. They form a central band, extending entirely across the country, and separating the north from the south of Italy. Since the acquisition of Ferrara, their eastern portion shoots a large branch northwards as far as the Po. They are thus in contact on one side with Tuscany and Lombardy, on the other with Naples. The Apennines pass entirely through them, producing on their borders some of the most beautiful scenery in Europe,—the lake of Perugia, the falls of Terni, the magic scenes of Tivoli and Frascati. These mountains divide the states into two unequal plains, of which the eastern is the most extensive, and contains the city of Rome; but it is in a great measure waste and pestilential. The western, comprising the Bolognese and the March of Ancona, is more fertile and better cultivated, but much narrower, being closely hemmed in by the Apennines and the Adriatic. The mountains produce timber, chestnuts, fruits, and even silk, wine, and oil, though not equal in quality to those of the Florentine and Neapolitan territories. There is very little manufacturing industry of any description. The annats, contributions, and indulgences, which anciently maintained the pontifical sovereign in such pomp, have disappeared with the decaying faith of the catholic world. He maintains about 6000 or 7000 troops, which are little better than a species of militia.

2672. *The population* of the Ecclesiastical States is about 2,600,000. Principal towns:—Rome, 150,000; Bologna, 65,000; Ancona, 30,000; Perugia, 30,000; Ferrara, 24,000; Ravenna, 24,000; Forli, 16,000; Pesaro, 14,000; Benevento (in Naples), 14,000; Ascoli, 12,000; Viterbo, 12,000; Macerata, 12,000; Urbino, 11,000; Loretto, 8000; Civit  Vecchia, 7000.

2673. *The revenue* is in a great measure conjectural, from the want of any official statements. M. Balbi, in a communication to the *Bulletin Universel*, states it to have amounted, in 1818, to 1,720,000*l.*: of which there was derived from land-tax, 400,000*l.*; from customs, 300,000*l.*; monopolies, 190,000*l.*; registers, &c., 200,000*l.*; lottery, 135,000*l.* At present the same writer estimates it only at 1,237,000*l.*, burdened with a debt of 24,700,000*l.*

2674. *Rome* (*fig. 310.*) is the capital of the Ecclesiastical States. This ancient city, still great in its decline, presents to the reflecting mind a more interesting spectacle than

the proudest capitals of the modern world. It holds enshrined, as it were, all the sublimest monuments of history and antiquity. Every spot is rendered sacred by awful names and heroic actions. The memory of those who rose in genius and glory above the rest of mankind, and of those whose nod fixed the destinies of the world, seems to hover around the "eternal city." Gibbon, while he disclaims enthusiasm as a part of his character, admits that it never left him during the weeks which he spent in wandering through the streets and monuments of Rome. Independent even of these high associations, Rome contains the most perfect works in architecture, painting, and sculpture, produced in the ages both ancient and modern, when those arts had reached their proudest height. Even now, all who wish to attain taste or perfect skill in those refined and beautiful arts, flock to Rome as their school. To celebrate Rome as it was, and as it is, libraries have been written; but we can merely mention those grand features which render it the admiration of the world.

2675. *The outlines of ancient Rome, and its relation to the modern city*, may be distinctly traced. Forsyth distinguishes three cities called Rome; that which the Gauls destroyed, that which Nero burned, and that which Nero rebuilt. The walls begun by Servius Tullius, and completed by Aurelian, present specimens of all the successive forms of construction which prevailed in Rome. The modern city is still enclosed by them; but it covers only a portion of the vast site occupied by the mistress of the world. It extends chiefly over the Campus Martius and along the Tiber, forming a curve round the base of the Capitol. The spectator must turn to the other side of that hill before he is met by the genius of ancient Rome. There, scattered in vast and shapeless masses over the seven

hills, appear its ruins. They stand in lonely majesty, with groves of funereal cypress waving over them. Its palaces, its tombs, its baths, its temples with their pointed obelisks, stand majestic but solitary monuments amid the extensive waste of time and desolation. The Palatine, which originally contained the whole city, which remained always its chief and most populous quarter, and is represented by Cicero as crowded with the senate, the orders, and with all Italy, presents a mere landscape with two solitary villas and a convent. The temples, palaces, and porticoes lie in such shapeless heaps, that the utmost learning of the modern architect and antiquary have been wasted in fruitless attempts to discover their plan and their site. Of the imperial palace only some vaulted subterraneous chambers of one wing remain. In general, it may be observed, that, with the exception of a few grand objects, the details of ancient Rome have escaped the most anxious researches of the learned. We cannot tell the site of many of the objects even most famous in antiquity. We cannot say, "Here stood the house of Mæcenas, of Cicero, of Horace." However, the Capitol, the Forum, the hills, are stamped with those characters of antiquity that cannot be mistaken: "a walk from the Capitol to the Coliseum comprises the history of ages." The leading features in Rome are the ancient edifices; the modern edifices; the works of painting; and the works of sculpture.

2676. *Of the ancient edifices*, though many retain only their rude foundations, and others have been so shattered, that their original form cannot now be traced, enough yet remains to inspire the most solemn emotions, and to give a full idea of the perfection of ancient architectural design. The monuments of Rome are divided by Forsyth into the works of the kings, of the republic, and of the empire. The first are of the solid and rude Tuscan order, with large uncemented blocks; but only a few detached specimens of them can now be traced. The works of the republic were almost strictly limited to objects of utility and power, — aqueducts, bridges, roads. It was not until the period of the empire, or at least until the liberties of Rome, undermined by the vast wealth of conquered kingdoms, were rapidly falling, that the arts of Greece, admired and imitated, enabled Rome to produce her perfect specimens of architecture. The orders were Grecian; but it is remarkable that, while the Doric and Ionic predominate in the original country, in Rome the highly ornamented Corinthian, of which the Composite is only a variety, was employed in all the principal edifices. Of these, the Pantheon and Coliseum remain nearly entire, or with

PANTHEON.

only such touches of ruin as render them more awful and picturesque. The Pantheon (*fig. 311.*), whose portico, it is said, "shines inimitable on earth," preserves uninjured this feature, its graceful dome and its pavement, and the rich fluted marble pillars that line its walls; while the deep tints of age only serve to render it more venerable. Yet Mr. Eustace laments it as shorn of its beams by the disastrous twilight of eighteen centuries; he regrets its proud elevation, the statues that graced its cornice, the bronze that blazed on its dome, the silver that lined the compartments of its roof within: but, on the whole, Mr. Forsyth conceives no monument of equal

antiquity to be so well preserved; which seems owing to its fortune in having been converted into a Christian church. The amphitheatre, called the Coliseum (*fig. 312.*), that spacious structure

"Which, in its public days, unpeopled Rome,
And held uncrowded nations in its womb,"

presents still the most gigantic monument of the Roman world. Fifty thousand people

COLISEUM.

could find seats in it; yet this huge space was, it appears, sometimes insufficient for the multitudes who thronged to witness the cruel spectacles there exhibited. This edifice, by its circular form, and the solidity of its materials, was enabled to defy the effects of barbarism; but it fell a victim to the hand of taste. The modern nobles, in seeking to adorn Rome with palaces, used the Coliseum as a quarry out of which the materials might be

drawn. The Farnese palace, one of its most boasted structures, is entirely built out of it.

The work of spoliation was arrested before it had stripped off more than half of this august edifice ; and from the frequent repetition of its parts enough remains to enable the architect to design a complete restoration. Some criticisms have been made on its details ; but on the whole it is allowed to be the most magnificent, and to excite the most solemn emotions, of any existing monument of antiquity. Baths form another most superb class of Roman monuments. Those of Caracalla resemble the ruins of a city rather than of any single structure. They afforded, in fact, every variety of recreation ; containing temples, porticoes, libraries, and theatre. It is supposed that there might be accommodation for three thousand persons to bathe at a time. The numerous columns, paintings, and statues, have been obliterated ; though, of the latter, the Hercules and the Toro Farnese were dug up from beneath. But the walls and many spacious apartments remain, and the general outline may still be distinguished. There are traces of a mosaic pavement, which appears to have extended over the whole. The baths of Diocletian are almost equally vast, but show a decline of the art ; a considerable portion of them is now converted into a convent of Carthusians. The baths of Titus are smaller than either ; but they appear to have been constructed in a purer taste, and beneath them was found the Laocoon, and the finest remains of ancient painting. The column of Trajan (*fig. 313.*) and that of Antoninus (*fig. 314.*) sur-

COLUMN OF TRAJAN.

COLUMN OF ANTONINUS.

vive as magnificent examples of this description of edifice. They are of the finest white marble, about one hundred and twenty feet high, and decorated with a series of sculpture, which winds in a spiral line from the base to the capital of each, representing their respective wars and triumphs. That of Trajan, in particular, contains 2500 figures ; forming a complete system of Roman antiquities, and a mine from which all modern painters have drawn materials. The two emperors have been deposed from their lofty shrines, and in their room have been elevated, with very bad taste, representations of St. Peter and St. Paul. Triumphal arches formed with the ancients a favourite mode of commemorating great actions and signal achievements. Of these, Rome still exhibits some splendid remains. The Arch of Constantine (*fig. 315.*) is the loftiest, the noblest, and in

ARCH OF CONSTANTINE.

the purest style of architecture. That of Titus is richer, but is considered by Mr. Forsyth as too much crowded with sculpture. Those of Severus and Gallienus are decidedly inferior. The tombs are lastly to be mentioned, as an object on which art and pomp were lavished by the ancients. Those of Augustus and of Adrian are on the most gigantic scale, and resemble subterraneous cities. The lower vaults of the former are large enough to serve for a modern amphitheatre ; but they were tombs on a hospitable system, destined to contain not himself and his relations

only, but his freedmen and all their families. That of Adrian, reduced to half its dimensions, still forms the Castle of St. Angelo, the spacious citadel of Rome. Greater elegance appears in the tomb of Caius Cestius, a lofty pyramid, which rises in lonely pomp, looking upon a hundred humbler tombs in the neighbouring grove, and supported on either side by the ancient walls of the city venerable in decay.

2677. *Of the modern edifices of Rome*, those devoted to ecclesiastical purposes are by far the most conspicuous; for, though Venice and Genoa may compete in the splendour of palaces, in churches no other city can be compared with this metropolis of the catholic world. They present also specimens of successive styles of architecture; many of them having been begun in the first centuries, and enlarged and embellished by a long line of pontiffs, till they have become perfect treasuries of wealth and art. Some of the series were not in the very purest taste; but as, even in the dark ages, they were often modelled after ancient structures which were always present to inspire ideas of grandeur, none of them exhibit marks of total degeneracy and deformity. "He, therefore," says Eustace, "who delights in halls of an immense size and exact proportion, in lengthening colonnades and vast pillars of one solid block of porphyry, of granite, of Parian or Egyptian marble; in pavements that glow with all the tints of the rainbow, and roofs that blaze with brass or gold; in canvass warm as life itself, and statues ready to start from the tombs on which they recline, will range round the churches of Rome, and find in them an inexhaustible source of instructive and rational amusement." Foremost among the churches of Rome, and of the world, stands the majestic front and sublime dome of St. Peter's (*fig. 316.*). On its site has always been the princi-

316

ST. PETER'S.

pal church of Rome, erected by Constantine, and rendered sacred by containing the ashes of the apostle from whom the bishops of Rome claimed their descent and authority. After being embellished during successive ages, it began to threaten its fall, when Nicholas V. and Julius II. conceived the project of erecting in its stead a new and nobler structure. It was carried on for a hundred years, by eighteen pontiffs, all devoting to it a large portion of their treasure, and employing upon it the talents of Bramante, Michael Angelo, Bernini, and other artists, the greatest of that most brilliant age. It is surprising with what unity the successive artists worked over each other's plans. The first, indeed, is liable to criticism; but the colonnade and the dome are perfectly unrivalled, and render it the most magnificent structure that ever was reared by mortal hands. The Basilica of St. Paul's is still more ancient, having been built by Theodosius, and presents great vestiges of ancient magnificence, consisting in painted walls, and long ranges of marble and porphyry columns. Though several times repaired, it has still, however, a forlorn, unfinished, and almost ruinous appearance; presenting the aspect of a desolate and melancholy monument. The church of St. John Lateran claims a still higher dignity; being, in preference to St. Peter's, the regular cathedral church of Rome; on which ground it assumes the lofty title of mother and head of the churches of the city and the world. It was, in fact, adorned with three hundred antique pillars, which would, it is supposed, have formed the finest pillared scenery in existence; but, unhappily, it came into the hands of a modern architect who seems to have been actuated by an antipathy to pillars, and who walled up a great proportion of them. The S. Maria Maggiore is another church, of which Eustace doubts if any architectural exhibition surpasses or even equals it. The two magnificent colonnades, and the canopy which form its interior, constitute its prominent beauties. Besides these four principal churches,

Rome contains numerous others, distinguished by their antiquity and embellishments, especially of painting and sculpture. The other leading ornament of modern Rome consists in its palaces. A fondness, and almost a rage, for erecting magnificent structures generally possesses the Italian nobles, and displays itself peculiarly in their town residences, which are hence usually dignified with the appellation of palace. So vast are those of Rome, that, with their appendages, they cover more ground than the modern habitations. They do not in general display the same lofty style of architecture as the churches or temples. Their place in the street does not allow room for the open gallery and spacious colonnade; and the external ornaments, even of the most splendid, consist chiefly in pilasters. Their chief attraction is in the spacious courts and porticoes within, the vast halls and lofty apartments, with the pillars, the marbles, the statues, and the paintings that furnish and adorn them in such profusion. Indeed, they are maintained in a great measure as galleries of painting and sculpture. These superb mansions are now in a state of decay: two of the most splendid, the Farnese and the Medici, belong to foreign princes, and are left under the care of stewards; while many of the great nobles, suffering under the hardships of the times, can no longer support the expense of keeping these vast mansions in repair, and have been obliged to dispose of some of their most valuable contents. The Barberini palace, erected by the cardinal of that name, with a noble library, opened on certain days to the public, contains many statues and pictures. The Farnese palace is considered the first in Rome for its architectural beauties, plundered, however, from the Coliseum: on its walls are painted the Gallery of Annibal Caracci, and the Galatea of Raphael; but its Torso and Hercules have been carried away to Naples. The Colonna, illustrious for the heroism and virtues of the family whose name it bears, is distinguished also by a gallery, the finest, perhaps, in Europe, adorned with Corinthian pillars and *giallo antico*; but the paintings of Claude, which formed its chief ornament, have been sacrificed amid the late distresses. The same fate has befallen the Claudes of Altieri. The Borghese has been celebrated for its profusion of works of art, particularly in sculpture; but these last, having been purchased by the Bourbons, remain at Paris. The Giustiniani, built on the site of Nero's baths, contains a vast profusion of statues dug up from beneath them. The Corsini is noted by its vast extent, its having been the residence of Christina queen of Sweden, and by its library, said to have amounted to 400,000 volumes. The Doria has a magnificent gallery, with many paintings, by the first masters; the Rospigliosi has the Aurora of Guido painted in fresco on its walls; and the Spada has the colossal statue of Pompey. The pontifical palaces, however, eclipse them all. The Vatican is pre-eminent, not by its external structure, which is simple, and not very uniform, but by its vast extent, being 1200 feet by 1000; by the number of its apartments, which have been estimated at 11,000; and, much more than all, by its contents, which are more precious and interesting than those of any other palace or edifice in existence. It contains the most valuable library in Europe, the finest works of Raphael and Michael Angelo, and a vast collection of ancient sculpture, including several of its choicest specimens. The thunders of the Vatican have ceased to agitate Europe, and this palace is now prized only as the great school of the peaceful and elegant arts. The summer palace on Monte Cavallo, the ancient Quirinal, is very extensive, but of simple structure, and has spacious and fine gardens. The Lateran is an elegant but smaller edifice, only used when service is to be performed in the neighbouring church.

2678. *The works of painting and sculpture* with which Rome is adorned, excel, as already observed, those of any other city in the world. The Roman school surpasses any in modern times in force and expression, the qualities which constitute the highest excellence of art; but, besides the works of Raphael, its leader, and of his disciples, the munificence of the pontiffs enabled them to attract the great masters from other cities of Italy. Michael Angelo, though a Florentine, executed scarcely any of his works at Florence; his Last Judgment, his Creation, his Prophets, are all painted on the walls of the Vatican. Of the school of Bologna, the Farnese Gallery by Annibal Caracci, the St. Jerome of Domenichino, the Aurora and Magdalen of Guido, rank as the best works of those respective artists. The series of Raphael's frescoes in the Vatican is probably the grandest in the world; for his Cartoons, preserved at Hampton Court, though equal in design, are comparatively unfinished. The choicest works of ancient sculpture having been employed to adorn the Roman temples and palaces, were dug up from beneath them to adorn the modern city: these, however, being all moveable, suffered still more than the paintings by the French system of spoliation, and all those which were of any value were carried away, that the Louvre might be made the centre of art. Even in the course of the restoration, several have been withdrawn. The Borghese collection, with its Hermaphrodite and Gladiator, remain, as already stated, at Paris; the Venus has been taken to Florence, and the Hercules to Naples. Rome, however, retains the Laocoon, the Gladiator, and a profusion of other works, still much superior to those found in any other city.

2679. *Modern Rome*, taken altogether, and independent of the many single majestic objects, cannot be called a fine city. The streets are narrower than those of London, though wider than those of Paris, and are covered with a reticular pavement, well suited for car-

riages, but annoying to the foot passenger. The houses are built of stone plastered with a species of stucco, which is extremely durable, yet can never convey to our minds the same ideas of richness and solidity. But the deadliest charge brought against Rome is its excessive dirt, in which it may vie with Lisbon itself. Filth is accumulated even in presence of the most majestic piles, to such an extent as renders them unapproachable to a nation so punctilious in this particular as the English. The whole pavement around the Pantheon is revolting to every sense, sprinkled with blood and filth, entrails of pigs, or piles of stale fish. Few vestiges remain of the 144 cloacæ, which were so salutary to the ancient city. The Roman Forum, which especially recalls such high associations, and is adorned with the most majestic ruins, being now converted into a cow-market, makes a profuse display of every description of filth. The population, however, has increased, in consequence of the resort of strangers, and is supposed to be nearly 150,000.

2680. *The villas in the vicinity of Rome* form an additional ornament to the city, especially the extensive gardens which surround them. The gardens of Lucullus, of Mæcenas, of Sallust, were peculiarly spacious and magnificent; and those of the modern palaces, though on a scale less vast, partake of the same character. Several command extensive views over Rome, anciently adorned with those stupendous edifices which were the wonder of the world, but now, perhaps, more interesting when the same edifices are lying on the ground, and overgrown with cypress. No spot commands so fine a view over these awful and immortal

VILLA BORGHESE.

remains as the Farnese gardens on the Palatine Mount. Of these villas, the Villa Borghese (*fig. 317.*) is the finest and most ornamented, and its walks, which, however, are too much in the old formal style, are open for the recreation of the public. The Villa Ludovisi contains the *Aurora* of Guercino; and the Villa Aldobrandini has the representation of a Marriage, which is viewed as the finest relic of ancient painting.

2681. *The more distant environs of Rome* consist, in the first instance, of that wide *campagna* or plain, which its pestilential air has devoted to almost total desolation. In approaching, however, to the branches of the Apennine, a singular variety of picturesque scenery begins to open. Gentle hills, with little lakes embosomed in them, and swelling into bold and lofty mountains, crowned with extensive forests; cascades dashing down their steep, and smiling plains intervening;—these, with brilliant skies and balmy airs, are common to this region with many others; but it derives peculiar interest from the edifices, noble in ruin, which adorn the brow of almost every hill, and from the recollection of the many illustrious ancients who in these shades wooed the Muses, and sought recreation from the toils of war and of empire. These features render this the peculiar region of the grand landscape, the scenes in which Poussin and Claude found the materials of their sublime compositions. An ingenious lady observes, that when she viewed these in England, she only exclaimed, “How grand!” but after seeing Italy, she added, “How natural!” Tivoli,

TIVOLI.

(*fig. 318.*) the ancient Tibur, the residence of Mæcenas, and Horace's favourite haunt, is celebrated over all Italy for its natural beauties. They consist chiefly in the windings and falls of the Anio, now Teverone, particularly the great fall, whose summit is crowned by the Temple of the Sibyl, a small edifice, but one of the most elegant and finely proportioned, which has been transmitted from antiquity. The river pouring down in two broad sheets, the rocks

fringed with shrubs, and crowned with forests, and with this beautiful ruin, produce a combination scarcely to be equalled. The temple stands, not very appropriately, in the court-yard of the inn, and the late Lord Bristol had made arrangements for purchasing and conveying it to England, when the Roman government prohibited the removal. The range of smaller falls, (*fig. 319.*) called Cascatelle, are equally beautiful, and adorned with the ruins of Mæcenas's villa, which still presents traces of its former magnificence. The country round Tivoli is as fertile

as beautiful, and still supports in the town a population of about 10,000 souls. There are several fine villas round it; but the Italians in general have little taste for rural scenery.

CASCADE AT TIVOLI.

Horace's villa stands higher up the river, amid the recesses of Mount Lucretilis, which Mr. Eustace considers so beautiful a combination of groves, rocks, hills, flocks and herds, as Arcadia itself could scarcely rival. Only part of a wall and some mosaic pavement indicate the spot. In a different direction is Frascati, on a hill near which Cicero had erected that beautiful villa, which was boasted as one of the eyes of Italy: it commanded a noble view of the plain of Rome, with the conspicuous and majestic feature of the Alban Mount rising behind. Not a vestige remains, except some pillars, which have been employed to adorn a monastery built on its site. The ruins of Tusculum appear scattered in long lines of wall, and of shattered arches intermingled with shrubs and bushes over the summit and along the sides of a mountain, on the lower declivity of which stands the modern town of Frascati. In this vicinity is the Lake of Albano, with waters clear as crystal, finely surrounded with

steep and richly wooded banks, and adorned by the noble edifice of Castel Gandolfo. Farther on is a solemn scene, the Lake of Nemi, anciently Nemus Dianæ, from the grove sacred to that goddess: it is small, seated in a deep hollow of the mountain, which it partly fills; the banks are not only wooded, but highly cultivated. In the centre of this lake, Trajan had moored a floating palace in the form of a ship, of which some fragments were dug up in the sixteenth century. We may also class with Roman picturesque scenery, though at a greater distance, the fall of Terni on the declivity of the Apennines. Here, as generally in Apennine scenery, the bold and grand are finely combined with the soft and the beautiful; the steep and rugged rocks being mixed with the verdure of the acacia, the laburnum, and a variety of other trees. The whole valley of the Nar, with the neighbouring one of Clitumnus, presents the Apennine in its mildest form, adorned with rich vegetation and beauty. The ruins of the ancient colony of Narni stand most romantically bosomed in groves on the top of a very high and steep hill, at the foot of which are some fragments of the proud arches thrown over it by Augustus.

2681. *Bologna* is by much the most important city of the Ecclesiastical State east of the Apennines. It is one of the most ancient and venerable places in Italy: its university, once said to have contained 10,000 students, and its school of painting, scarcely second to those of Rome and Venice, have raised it to distinction as a seat of learning and art. After passing in its republican state through many turbulent revolutions, it voluntarily, in the thirteenth century, united itself to the Roman state; stipulating, however, for the preservation of many of its privileges. It had still a senate of forty hereditary nobles, presided by a gonfaloniere, besides a popular body, which superintended matters of revenue and police. A republican spirit, however, always prevailed in Bologna; and in 1796, it gave to the French army a welcome, which met with the usual return; the city being deprived of all its constitutional rights, and assimilated to the despotic sway established in the kingdom of Italy. The Pope, in 1815, was reinstated in possession of it by the arms of the Allies; but, to the just discontent of the city, he declined restoring any of its privileges, and continued the same absolute sway which had been established by Napoleon. However, though oppressed and fallen, it retains still many features of the learned and opulent Bologna of the middle ages. Its territory forms a continuation of the great plain of Lombardy reaching to the Apennines; and it is as laboriously cultivated, and the peasantry are apparently in a more joyous and happy condition. The city is well built, with long lines of arches and columns, affording beneath a paved walk to foot passengers; an accommodation rare in Italy, and an object of envy. The principal church is that of St. Petronius, a spacious, though not a beautiful Gothic edifice. That of St. Dominic is celebrated for its shrine, which occupied the chisel of Michael Angelo and Nicolo; and for a collection of pictures, which have since, however, been transferred to the Institute. There is also a highly ornamented church, dedicated to the Virgin, situated about five miles from the city. The palaces are spacious, and distinguished both for their architectural beauty and the works of art which they contain; but those of the Zampieri, the richest of all, have been transferred to the Brera collection at Milan. The university does not at present number more than 500 students; yet its professors are still eminent, and most of the science which still exists in Italy centres at Bologna. But the great modern boast of this city is the Institute, formed in the seventeenth century, chiefly through the exertions of two of its noble citizens, Count Marsigli, a general in the imperial service, and Count Manfredi. At their instance, the city

purchased the palace *Cellesi*, one of the most spacious in Bologna, in which are now accommodated the Academy of Sciences founded by Manfredi, which has brilliantly maintained its reputation; a library of 150,000 volumes; various scientific collections; and a gallery of paintings, in which, as well as in the churches, are seen numerous specimens of the great Bolognese masters; the three Caraccis, Guido, Domenichino, and Albano. Here instructions are also given to young artists.

2682. *Ferrara*, the celebrated seat of the princes of Este, who made themselves so prominent as the patrons and persecutors of the learned, is large, dark, and antique. "The long and spacious streets, silent, solitary, and grass-grown, give it the solemn air of a deserted city." The castle of the duke, that grand theatre of feudal pomp, is a vast structure, with lofty towers, and surrounded by a broad ditch, in the very heart of the city. Ferrara has many spots which recall interesting but painful recollections: the cell of the hospital of St. Anne, in which Tasso was so barbarously immured; the dungeons in which several votaries of the Reformation perished; the tomb of the oppressed and injured Ariosto.

2683. *Other considerable and interesting cities* distinguish this coast. Ancona, the principal naval station of the Romans on the Mediterranean, retains its admirable port, capable of accommodating commerce of any extent, and in fact carrying on most of the little which belongs to the patrimony of St. Peter. The magnificent mole erected by Trajan to cover the port still remains, and is considered the finest work of the kind extant. Rimini is a place of high historical memory. It was conquered by Belisarius, and in the middle ages was one of the chief stations of the predatory bands. The city is still standing. Condottieri with its castle, converted into a Roman barrack, presents still a romantic aspect. Fano, the scene of Asdrubal's defeat, Pesaro and Sinigaglia, are agreeable country towns, rendered gay by the residence of numerous nobles. Loretto has long excited the admiration, and been the resort of the whole catholic world, from a legend reckoned among the surest in the Roman calendar. The house of the Saviour's nativity, after Palestine fell into the hands of the infidels, was, it seems, carried miraculously through the air by angels, and established in this favourite city; princes, prelates, and princely dames, undisturbed by any profane doubt, flocked from every part of Europe to contemplate and pay their adoration to so holy an object; the sacristy was heaped with treasures; the mean hovel was encased in sculptured marble, and the black wooden Madonna loaded with gold and jewels. Her crown of diamonds, however, and all her accumulated treasures, were plundered by the impious hands of the French republicans, and appropriated to the military chest. She was reinstated after the battle of Waterloo, when the Pope and the king of France gave her a new velvet gown, and a considerable number of diamonds. Loretto, however, is no longer enriched by pilgrims, most of those who now resort thither beg their way, and must be supported at the expense of the church. A pretty brisk trade is, however, driven in beads, rosaries, crucifixes, and relics. The town is otherwise poor, and swarming with beggars. We must not quit the papal territory, without noticing what has been called the freest and most virtuous of all commonwealths, that formed on the insulated rock of San Marino. Founded by a man of low rank, and having become a refuge for those who sought peace amid the turbulence of the feudal ages, it has remained inviolate for thirteen centuries, either respected or overlooked by the proudest and most mighty oppressors of Italy. It has still "Liberty" inscribed on the gates of its little capitol, and exemplifies, in the virtue, simplicity, and happiness of its people, the powerful influence of free institutions.

SUBSECT. 2. *Tuscany.*

2684. *The Duchy of Tuscany* ranks next to the Roman states as the theatre of great historical events, and has surpassed Rome itself as the seat of modern learning. Its first glories even preceded those of the metropolis. The Etruscans, the earliest masters of Italy, were found by the Romans divided into ten powerful, brave, and, in some respects, civilised commonwealths. They were vanquished, however, and so completely destroyed, that the antiquary seeks in vain to fix the site of Veii, Fidenæ, and of the other large and strong cities, on which flocks have now fed for more than 2000 years. Under Rome, Etruria, though held in some veneration as a seat of early religion and learning, never reached any political importance. Amid the tumult of the middle ages, however, there arose in it a cluster of proud republics. Florence, Pisa, Sienna, Pistoia, acquired distinction for their wealth, their valour, their lofty spirit of independence, and their zealous cultivation of the arts and sciences. Under the influence of freedom, they performed achievements and erected monuments on a scale much beyond their narrow territory and limited population. By a series of revolutions, internal and external, these states have been stripped of all their greatness and glory, and united, notwithstanding their deadly hatred of each other, under the sway of a prince of the house of Austria. The yoke, however, has been mild, and, under Leopold, was singularly beneficent. Little, indeed, remains of the commerce and industry by which Florence was formerly so distinguished; but the vale of the Arno, the plain of Pisa, and the environs of Sienna, are still as highly cultivated and productive as any part

of Europe. The arts of painting and architecture are fallen from their ancient eminence, but the monuments of them remain, and are rendered more interesting by the tints which time has thrown over them. Tuscany contains about 1098 square leagues; and in 1826 had 1,275,000 inhabitants. Principal towns:—Florence, 80,000; Leghorn, 66,000; Pisa, 20,000; Sienna, 18,000; Prato, 10,000; Pistoia, 9000; Arezzo, 7000; Cortona, 5000.

2685. *Florence* (fig. 320.), which attained so great a name under the humane and enlightened

sway of the Medici, is still a delightful city. Its situation is peculiarly happy, in the vale of the Arno, which forms one continued interchange of garden and grove, enclosed by hills and distant mountains. Its public buildings are fine, though all modern. Being surpassed by those of Rome, they no longer excite any peculiar interest. The cathedral,

however, while St. Peter's was not yet constructed, ranked as the most majestic edifice in Italy; and the form of its dome is supposed to have at least suggested that of the other more majestic one. The palaces, also, with the same character, have a similar uniformity; and many of them, erected during the ages of dire and deadly feud, exhibit, in their approaches at least, an attention to strength rather than to beauty. The Gallery is the chief pride of Florence, both as to its structure and contents. It has twenty apartments branching off from it, in each of which the productions of a particular school or class of art are exhibited. In ancient sculpture this collection has perhaps no rival, since it contains the Venus brought from the Medici palace, the group of Niobe, the Faun, and many other masterpieces. The paintings are so arranged as to form a complete history of Italian art, from the era in which it was a mere object of curiosity to that when it was displayed in its full splendour. It comprises also some of the greatest masterpieces of Raphael, Titian, Andrea del Sarto; and is adorned with some of those belonging to the principal schools beyond the Alps. The French, having selected and carried off sixty-three, left it completely shorn of its ornaments; but those have now all resumed their places. There are few paintings, but pretty numerous sculptures by Michael Angelo, especially those which adorn the tomb of the Medici.

2686. *The environs of Florence* are nearly as romantic as those of Rome, and not separated by any intervening desert, but rising in its close vicinity. Vallombrosa, a grand and solemn scene, where "Etrurian shades high over-arched embower," has been rendered classical by the immortal verse of Milton, who is supposed to have drawn from it his picture of Paradise, when he describes it —

——— "shade above shade,
A woody theatre of stateliest view."

Fiesole, on an eminence, commands an enchanting view of Florence and the vale of Arno. Once the rival of that city, it is now a lonely and delightful village, and was the favourite spot to which the greatest men of Florence retired for the enjoyment of rural contemplation. Milton refers to the top of Fiesole as a happy point for observing the phenomena of the heavenly bodies. More remote, and approaching to the greatest height of the Apennine, the sacred hermitage of Camaldoli stands in a valley; but on the hill above, are twenty-seven little mansions, each the abode of one monk, who, detached from the abbey, spends two years in austere and lonely retirement. Fourteen miles higher up, amid the most solitary and savage recesses of the Apennine, is the Franciscan convent of Lavernia, containing eighty friars. It is seated on a lofty rock, broken into numberless pinnacles, while thick groves, rising to the summit, and nodding over the steeps, cast a rich and mellow shade upon the whole scene.

2687. *Pisa*, situated in a fertile and beautiful plain, was long one of the proudest and most prosperous of the commercial republics of Italy. Subjected by Florence, after a long contest, and now involved in the same common slavery, her wealth has disappeared, and her population has been reduced from 100,000 to 17,000. A solemn character of fallen grandeur still invests her. Her four edifices, the cathedral, the baptistery, the leaning tower, and the Campo Santo, form one of the grandest existing ranges of architecture, all built of the finest marble. The style is not altogether pure, being usually termed the *Moresco Gothic*; but Mr. Forsyth is rather of opinion that it is a mere corruption of the Greek model, retaining, however, much beauty. The cathedral is the most spacious and splendid of these edifices; but the campanile, or belfry, is the most remarkable. It is a tower of six successive stories of arches, supported by pillars. But its grand peculiarity is, that it has actually deviated fourteen feet from the perpendicular, yet has thus stood for 300 years, without the slightest tendency towards a fall. The deviation appears to have

been in consequence of the softness of the ground, but it is a striking proof of skilful and solid construction, that this lofty edifice has not only remained firm for so long a period, but does not even now give the least menace of ruin.

2688. *Sienna*, after acquiring a great name among the Italian republics, sustained a fate similar to that of *Pisa*. It is situated in a hilly and even mountainous country; which, however, yields abundantly the olive, the vine, and in many places grain. The *Monte Pulciano* and *Chianti* grapes give a wine superior to what is usually found in Italy. The southern district, however, consists of *maremma*, connected with the great Roman one. The nobles reside chiefly in the city, in the usual effeminate manner, and still retaining a remnant of those deadly feuds by which their order was formerly rent. It has some remains of the once extensive silk manufactory. *Sienna* had a respectable secondary school of painting, of which *Vanni* and *Peruzzi* were the heads; but its most remarkable monument is the pavement of its cathedral, the work of *Micarino* and other artists, who, by the mere combination of white and grey marble, hatched with mastic, produced the effect of the finest mosaic.

2689. *Leghorn* is almost the only modern and prosperous town in the compass of the Tuscan territory. When ceded by *Genoa* in 1421, it was only a petty village; but the able arrangements of the *Medici* raised it to the rank it has since held as the first commercial city of Italy, and the great centre of Mediterranean commerce. It is airy and well built, with broad streets, fourteen churches, one Armenian, and two Greek chapels, and even a magnificent synagogue; the necessary toleration of commerce overcoming even Italian bigotry. There are, however, no edifices which excite any recollections of antiquity, or can compare with those which adorn the other cities of Italy.

2690. In the rest of *Tuscany* we may remark *Cortona*, the ancient capital of *Etruria*, supposed to be the most ancient city of Italy. The antique walls still remain as the substruction of the modern ones; and their vast uncemented blocks, which have subsisted for ages, mark the solidity of Etruscan masonry. *Cortona* is now reduced to 4000 inhabitants; but it is distinguished by the Tuscan Society, which has done much to illustrate the antiquities of *Etruria*. *Perugia*, also an ancient Etrurian state, is still a clean pretty town, delightfully situated on the lake of that name. *Arezzo* is a name rendered classic by the birth of *Petrarch*, of *Redi*, and of *Pignotti*. *Bibbiena* is a thriving little town, in the centre of the *Casertine*, inhabited by an industrious peasantry, who are reckoned to have the best hogs and the best chestnuts of all Italy.

2691. *Lucca*, though an Etruscan city, is now governed by a duke of its own. It is one of the few Italian republics which, amid the revolutions of 800 years, maintained its independence. The *Lucchese* reaped the benefit of this, in the superior education and more decent deportment of her nobles; in that agricultural industry which, in a degree even beyond what appears in the rest of Italy, has converted a land liable to inundation, and destitute of many natural advantages, into a complete garden. The territory, though only forty-three miles in length and twelve in breadth, two-thirds of which consist of mountain and defile, reckons a population of 140,000, being 328 to the square mile; a density which has no parallel, even in the most fertile plains of the rest of Italy.

SUBJECT. 3. *The Lombardo-Venetian Kingdom.*

2692. *Austrian Italy, or the Lombardo-Venetian Kingdom*, consists of the great plain of the *Po*, bordered on one side by the highest ranges of the *Alps*, on the other by those of the *Apennines*. It has not the classic sites and monuments of *Rome*, nor the brilliant skies of *Naples*; yet it would be difficult to find on the globe a territory of the same extent equally fine. The luxuriant fertility of this vast plain; the grand, almost magic, landscapes presented by the southern declivity of the *Alps*, and the lakes which spread at their feet; the fine shores of the *Adriatic*, unite in making it one of the most desirable regions of Europe. It is an aggregate of several portions that were politically very distinct. The duchies of *Milan* and *Mantua* were always ruled by feudal sway, and under a dependence on the German empire; but *Venice*, the greatest and mightiest of the republics which rose when Europe began to emerge from the darkness of the feudal ages, continued long the equal and rival of the greatest monarchies. This high pre-eminence gradually departed with the energies by which it had been supported; and *Venice*, as a republic, was little more than a phantom, when the French revolutionary force first subverted it, and afterwards basely, but in just reward of its pusillanimity, delivered it over to *Austria*. Afterwards, through the ascendancy of *Bonaparte*, the whole of *Lombardy* was absorbed in his kingdom of Italy, of which *Milan* was made the capital seat. Subsequent and well-known events reversed all these arrangements; and this part of Italy was restored entire to *Austria*. That power, in 1815, erected the whole into what was called the *Lombardo-Venetian Kingdom*, and granted to it a certain form of representative constitution. The members are chosen partly by the landed proprietors, and partly by the nineteen royal cities: they form two central congregations, meeting one at *Milan*, and the other at *Venice*. The election,

however, is limited, the government choosing out of a list of three presented to it, and even claiming the right of expunging from the office of elector such as it deems unworthy to exercise it. This body has the distribution of the taxes, and also of the military levies over the different districts; though the general amount of both is determined, without any reference to them, by the court of Vienna. It has the superintendence of public works, charitable establishments, and other local objects; and may propose the means of raising funds for their support. These privileges, such as they are, no doubt produce great benefits to the country; though, as the congregation has not even a negative voice in the making of laws and imposing taxes, it can fulfil very imperfectly the representative functions. It is also a subject of complaint, that all offices, even judicial, are exercised by Germans, a nation whom the Italian hates and despises as barbarian. The state of agriculture, and of the other branches of national industry in Lombardy, has been sufficiently illustrated in describing those of Italy in general, in which it forms so prominent a part.

2693. *Government of Milan.* Population, 2,280,063. Principal towns:—Milan, 151,000; Brescia, 31,000; Cremona, 26,000; Mantua, 25,000; Pavia, 21,000; Lodi, 18,000; Como, 7600.

2694. *Government of Venice:* 1,957,229. Principal towns:—Venice, 101,000; Verona, 48,000; Padua, 35,000; Vicenza, 19,000; Udina, 18,000; Treviso, 15,000; Belluno, 8000; Rovigo, 7000.

2695. *Parma:* 440,000. Towns:—Parma, 30,000; Placentia, 28,000; Guastalla, 5000.

2696. *Modena:* 350,000. Towns:—Modena, 27,000; Reggio, 18,000; Mirandola, 6000.

2697. *Milan* is a noble city, which ranks almost as the modern capital of Italy. Its situation in the middle of a superlatively rich and beautiful plain, watered by the Po, at a point where all the great canals meet, and on the high road from Germany by the lakes Maggiore and Como, render it a sort of key to the northern part of this kingdom. Its modern greatness preceded that of most of the other cities; and under the Sforzas and Viscontis it became the grand theatre of debate between France and Austria. Its greatest splendour, however, was attained under the régime of France, when it became the capital, first of the Italian republic, and then of the kingdom of Italy. Napoleon spared no expense in erecting edifices which might dazzle the eyes of his new vassals. The Duomo, (*fig. 321.*) begun in the fifteenth century, under the Viscontis, and slowly carried on by

321

MILAN CATHEDRAL.

successive benefactions, had been left more than half unfinished; so that the French had the greater part of its magnificent front to execute. It is the only very superb edifice of this description which may be said to belong to the present age. In extent and pomp it ranks second to St. Peter's; though the design has been criticised, especially as to the four hundred statues which are ranged along the façade. It is 454 feet long, 270 wide, the height of the cupola is 232, and that of the tower 335 feet. The French have also erected a very magnificent amphitheatre, completely on the antique model, in which from 30,000 to 40,000 spectators can

be accommodated. Chariot races and national games have been repeatedly performed within its precincts. A superb triumphal arch was commenced on the Simplon road, in commemoration of the stupendous labours by which that passage over the Alps was formed; but since the fall of Napoleon no further progress has been made. The theatre Della Scala is the only very fine one in Italy, as it was only in Milan, and during the last century, that the Italian drama acquired any degree of splendour. The opera of this city is accounted inferior to that of Naples; but the ballet is the finest in Italy, and consequently in the world. A more interesting and classical scene is presented by the Brera, or palace, formed out of the ancient convent of the Humiliati. Here the French deposited the finest paintings which could be procured by purchase or otherwise from every part of Italy, including those brilliant productions of the Bolognese schools, which had adorned the Zampieri palace. The Last Supper of Leonardo da Vinci, one of the greatest masterpieces of modern art, and long the pride of Milan, is now almost entirely faded, and scarcely known but by engravings, and by a very fine copy, in mosaic, made by the French. The Ambrosian library, formed by Cardinal Frederic Borromeo, on the basis of the Benedictine collection, consists of 90,000 volumes and 15,000 manuscripts, and is well known to the world by the learned researches and discoveries of Angelo Mai. Milan has an infirmary for 3600 sick,

and a foundling hospital for 4000 children. It covers a great space of ground, and has some very spacious squares; but the streets in general, like those of other old cities, are narrow and crooked, and far from handsome. Several of those called *corsos*, however, which form the entrance into the city, have been greatly improved.

2698. *Venice* (fig. 322.), though now reduced to a secondary rank, compared with Milan,

322

VENICE.

is a more celebrated and still a much more beautiful city. This once great republic, into which flowed the commerce and wealth of the East, which ruled the Mediterranean, sacked the imperial city, and set bounds to the Ottoman power, at a moment when it seemed ready to overwhelm all Europe, is now, after a duration of thirteen centuries, for ever extinguished. Its fall without a struggle was, doubtless, prepared by a decay of its moral energies. The nobles

who once swayed the councils of Venice, and commanded her fleets, had no longer any object but to attend public processions, to pay court to their lady, to while away the evening at her casinos, and to heighten the gay licence of the carnival. The people, enslaved, had lost all national spirit. The republic of Venice, with all its bright series of triumphs, is now an empty name; it remains, however, next to Rome, the finest of all the Italian cities. It cannot, indeed, boast of any classic monuments, nor are its churches built in so lofty a style; but its palaces, the gay architecture of Palladio, present a range of the finest private mansions that were ever erected. The effect is greatly heightened by its situation, on seventy islets of the Adriatic, partly on the rock, partly on piles sunk into the sea, and a marine channel, instead of a pavement, perforating every street. Scarcely is there room left for a foot passenger; the Venetian is conveyed in the gay gondola from palace to palace. Thus Venice appears rising from the waters, with its numberless domes and towers; and, attended by several smaller islands, each crowned with spires and pinnacles, presents the appearance of a vast city floating on the bosom of the ocean. The row of magnificent but decaying palaces which extend along the grand canal, with their light arabesque balconies and casements, their marble porticoes, and peculiar chimneys, present one of the most superb and singular scenes in the world. They stand in majesty of ruin, and exhibit the most affecting combinations of former splendour and present decay. The most commanding objects are those round the square of St. Mark, the most magnificent public place in Italy. The church of St. Mark rivals in splendour any edifice in that country, or in Europe. But this pomp is gloomy and barbaric: the five domes which swell from its roof, the crowded decorations which cover its porticoes, give it the appearance of an Eastern pagoda. Its mixed orders, Greek, Saracenic, and Gothic, are beautifully but barbarously blended, and glitter with incrustations of gold, gems, and marbles. The interior is enriched with the spoils of Constantinople and the East, the monuments of long ages of glory. The most classic plunder is that of the four bronze horses of Lysippus, which stand on the portico facing the piazza. After remaining there six hundred years, they were removed to the Tuileries, but are now replaced. The figure of a lion, emblematical of the evangelist St. Mark, stands on the second arch. One side of the square is lined by the ducal palace, a fabric of vast extent and solidity, built in the Gothic and Saracenic style. The stranger beholds with emotion the halls where the senate, and the dreadful Council of Ten formerly sat; and which, as well as the other apartments, are adorned with the finest works of the Venetian painters. The Rialto, a bold marble arch thrown over the most magnificent part of the great canal, excites universal admiration. The arsenal occupies an island by itself, and is strongly fortified, spacious, and commodious, wanting nothing but shipping and naval stores. The churches, the palaces, and the *scuole* or halls of the different corporations, are embellished with the finest paintings, both in oil and fresco, of the great Venetian painters, Titian, Paul Veronese, Tintoretto, and the Palmas. This school, as is well known, surpassed all others in colouring, though it did not reach the grand design and expression of the Roman. Venice is the birth-place of Canova, the greatest of modern sculptors, and contains some of his works.

2699. *The Venetian territory* can boast several renowned cities. Padua, which is said to have been founded by Antenor, and to have attained considerable magnitude before the existence of Rome, gained celebrity in modern times as a seat of learning. Its university was only rivalled by that of Bologna, and attracted 18,000 students; yet, though it has still forty-five professors, and affords ample means of acquiring knowledge, the scholars were in Eustace's time reduced to 600; and, according to Hassel, in 1817 they did not exceed 300. Galileo, Vesalius, and Morgagni were among its professors; Livy and the modern

historian Davila were born there; and Petrarch is buried at Arquà, in the vicinity. The city is divided into two parts: the old, composed of dark narrow streets, and high old palaces; and the modern, adorned with the splendid architecture of Palladio. The university, and the church of Justina belong to the latter, and are fine edifices. Vicenza, the birth-place of Palladio, has been adorned by him with about twenty palaces, perhaps the most beautiful in Italy, besides other public buildings, among which the Olympic Academy, founded for the cultivation of literature, deserves particular mention. Verona, an ancient and still a large city, the close ally rather than the subject of Venice, attracts admiration by its ancient amphitheatre, the largest remaining except the Coliseum, to which it is inferior in size only. In recent times Verona has attracted notice as the seat of a congress, which disposed of the fate of Italy. Brescia and Bergamo are considerable towns in the lower Alpine districts, but more remarkable for industry and manufactures, of which they still retain a considerable share, than for splendour or embellishment.

2700. *Among the other cities of Lombardy*, Mantua takes the lead: it is still large, and forms one of the strongest fortresses in Italy. Pre-eminently classical as the birth-place of Virgil, it made a considerable figure in modern times, both as a republic and under its dukes of the house of Gonzaga. Cremona, the birth-place of Vida, is a large and well-built city, containing many handsome edifices. Pavia is the seat of an ancient university, supported and attended by 600 or 700 students. It is still better known by the great battle fought in its vicinity between the French and Germans, in which Francis I. was totally defeated and taken prisoner. Lodi is a large fortified town, distinguished as the seat of one of Bonaparte's most splendid victories.

2701. *Parma, Placentia, and Guastalla*, though they have been nominally formed into a state for the ex-empress of France, form in reality a complete appendage of Lombardy, and a continuation of its great plain, to the foot of the Apennines. They abound in the richest pastures, from which is produced that most celebrated of cheeses, to which Parma gives its name. The dukes of Parma, and especially the celebrated Alexander Farnese, have ranked among the first generals of Europe. The city of Parma, on a small river of the same name, is large, populous, airy, and clean. It does not contain any remarkable architectural features, except the theatre, modelled on the ancient plan, and perhaps the noblest in the world, but now in a state of decay; but Parma can boast a school of painting, one of the finest and most interesting that ever existed; in which grace was the predominant feature. The chief masters were Correggio and Parmegiano, whose works in fresco adorn the walls and cupolas of the churches in Parma; and the oil pictures, which the French carried off, have now been restored. Placentia is also a large and well-built city; but its celebrated amphitheatre, which surpassed that of Verona, was burnt to the ground in one of the furious civil contests which laid waste Italy. The banks of the Trebbia, in its vicinity, have been the scene of two of the greatest battles recorded in history; one gained by Annibal over the consul Sempronius; the other by Suwarrow over Marshal Macdonald, which decided for a time the fortunes of Italy. *Modena* is a fine small domain, composed of a rich plain at the foot of the Apennines. It is held as a fief of Austria, and by a branch of that family, with the title of duke. The city of Modena, the ancient Mutina, is extremely handsome, though without any objects peculiarly striking. It was enriched by the family of Este with splendid collections of books and paintings; but the latter have been now removed, by purchase, to adorn the Dresden gallery. The territory of Massa-Carrara, held at present by the Archduchess Maria Beatrix, will on her death fall in to Modena.

SUBSECT. 4. *States of the King of Sardinia.*

2702. *The Sardinian States* are of very dissimilar character, but united by political circumstances under one government. The dukes of Savoy, founders of the Sardinian family, made a conspicuous figure in European history, especially during the war of the Spanish succession. In return for their services to the cause of the allies, they were recompensed with the island of Sicily. That island was afterwards, in consequence, it should seem, of a very bad bargain, exchanged for Sardinia, from which the house assumed the royal title. Under the domination of Napoleon, the king was expelled from all his Italian territories, and owed to British protection alone the preservation of Sardinia. After the triumph of the allies, he was not only replaced in all his former possessions in Italy; but the state of Genoa, instead of being restored to its lost independence, was subjected to his sway. The kingdom of Sardinia consists, therefore, of four distinct parts,—Piedmont, Genoa, Savoy, Sardinia.

Population.		Principal Towns.	
Savoy	- 467,080	Chambery, 12,000.	Annecy, 5500. Morienne, 2500.
Piedmont	- 2,363,170	Turin, 114,000.	Alessandria, 80,000. Asti, 20,000. Mondovì, 17,000. Vercelli, 16,000. Nice, 15,000. Novara, 13,000. Voghera, 10,000. Coni, 9000
Genoa	- 539,150	Genoa, 80,000.	Savona, 10,000. Novi, 8000.
Sardinia	- 461,950	Cagliari, 27,000.	Sassari, 19,000.
3,831,350			

2703. *Pieamont*, or "the foot of the mountains," is the most valuable possession of this crown. It forms a continuation of the plain of Lombardy, somewhat narrowed, and more closely bounded by the mightiest ranges of the Alps and Apennines; the former on the north and west, the latter on the south. The Po, running through its centre, divides it into two nearly equal parts, and receives here all its early tributaries; which, being so near their mountain sources, are liable to sudden and terrible inundations, distressing to the agriculturist and dangerous to the traveller. The chief produce is silk, which is reckoned superior to any other in Italy, and consequently in Europe; and in Turin and some other cities remains exist of very extensive silk manufactures; but the greater part of the produce is exported raw. The government is absolute, but tolerably mild; and a recent attempt to establish a constitutional form was speedily crushed by Austrian interference.

2704. *Turin* maintains its place among the beautiful cities of Italy. Its situation is as fine as possible, amid the rich valley of the Po, surrounded by an amphitheatre of vine-covered hills; while lofty mountains, with their summits clad in perpetual snow, tower in the distance. The streets are long and regular, ornamented with lines of porticoes, and opening at their terminations to fine views over the surrounding country: it is a little city of palaces. The churches and mansions are spacious, and of rich materials; but few display that classic taste in which real beauty consists, and which ennobles the Roman and Venetian structures; the vases of pure gold, the silver images, and the crosses of ruby, were all converted by French avidity into current coin. The most striking edifice is the church of the Superga, built on the steepest hill which crowns the city. The ancient palace of the dukes of Savoy is a huge brick edifice, resembling a fortress rather than a palace. Turin has a considerable number of paintings, not marking any particular school, as none ever arose in this part of Italy, but chiefly composed of Flemish and other ultra-montane productions. The university is very extensive, and contains important collections, among which those of natural history, natural philosophy, medals, and antiques, are particularly noticed. The library is also rich in curious works and valuable manuscripts. The citadel of Turin forms a very strong fortress.

2705. *The other cities of Piedmont* are chiefly remarkable for their strength, having been erected when this country was a seat of almost perpetual war. The strongest is *Alessandria*, built in the twelfth century, at the junction of the Bormida and the Tanaro. It is large and very strong; besides which, the town is the seat of extensive fairs. Near it is the celebrated field of *Marengo*. The once strong fortifications of *Tortona* have been demolished. *Vercelli*, the former capital of this part of Italy, and distinguished by some fine structures, is now thinly inhabited and dreary. *Novara* is a gloomy antique frontier town towards Lombardy. *Coni*, among the Alps, is considered the bulwark of the kingdom on the side of France. *Susa*, once the capital of Piedmont under its marquises, is a retired pleasant little town, on the immediate frontier of France. *Nice* is the capital of a little country scarcely Italian, being beyond the Alps. Though it cannot be said to be well built, it is agreeable; and, as the environs are beautiful, and the air mild, it is a frequent resort of English invalids.

2706. *The territory of Genoa* is situated on the sloping steeps of the Apennine, where it separates from the Maritime Alps, and stretches eastwards; not separated from the sea by a broad plain, as in the rest of its line, but presenting to it narrow valleys and mountain declivities facing the south. These steep barriers are passable only at a few points; and the *Bochetta*, a very steep and lofty defile, forms the only practicable approach to Genoa from the interior. This district, the country of the ancient Ligurians, is not favourable for the operations of the plough; but olives in abundance, silk, and tolerable wine, are advantageously produced from it.

2707. *Genoa* (*fig. 323.*), surnamed *the Superb*, the great naval republic which, in the

GENOA.

annals of Italian wealth, commerce, and splendour, ranked only and scarcely second to Venice, presents but a shadow of her former greatness. Her navigators were of a peculiarly bold and adventurous character; and she was the native city of Christopher Columbus. Her settlements in the remote peninsula of the Crimea enabled her to bring into

Europe, by a peculiar and circuitous route, the commodities of India. Depressed by a once haughty and now indolent aristocracy, and eclipsed by the rivalry of the northern nations, Genoa had lost all her principles of prosperity, before her independence was crushed by the revolutionary arms of France. Yet it seems impossible to applaud the conduct of the Allies,

in annexing her to Sardinia, though with permission to preserve her senate and outward forms of administration. The wealth of the great days of Genoa was, as usual, embodied in palaces. These are arranged in one continuous line of street, extending under three different names through the city, all the rest of which is a mere chaos of dark and dirty lanes. These palaces are boasted as being, for richness of materials and profuse ornament, the most splendid in Italy, and many of them are every way fit to be the residence of the greatest monarchs. They have one ornament peculiar to themselves, which consists in fresco paintings on the exterior of the walls, many by masters of some eminence; and, in this fine climate, these remain unimpaired for centuries. The design, however, both here and in the churches, wants that elegance and purity of taste by which the structures of Venice have been rendered so admirable. Ornament and glare seem to have been the ruling passion of the Genoese. Her nobles, though all sunk, and many reduced to poverty, would spend their last farthing in supporting the pomp of their ancient mansions. Hence these have now a silent and desolate aspect, and have been compared to the ruined monuments of an excavated city. They are filled with pictures, gilding, arabesques, frescoes, dust, moths, and dirt; exhibiting a combination of ancient splendour and present decay. Genoa has not altogether the magical effect produced by the long lines of canal which intersect Venice; but her position, occupying one side of the spacious amphitheatre which forms the harbour, and spreading her streets and churches, and then her suburbs and villas, over a vast semi-circular tract of crags, rocks, and declivities, gives her, towards the sea, a highly magnificent and imposing aspect. The city has also the disadvantage of being so closely bounded by rocks, that no level spot is left on which a carriage can drive; and the neighbouring villas can be reached only in chairs carried by a species of porters, endowed with singular agility and alertness. Genoa, though fallen from her ancient greatness, is still considerable, and has of late even somewhat increased. She manufactures rich velvets, damasks, and satins, to the value of from 200,000*l.* to 300,000*l.*; and she carries on the trade of the Sardinian dominions in Italy, and partly that of Switzerland. She exports her own manufactures, olive oil in abundance, rice, cheese, thrown silk, and Swiss printed cottons. The productions of the Levant and of Southern Italy are found in her warehouses. She imports salt fish, British cottons and woollens, grain, wool, cotton, and colonial produce. Among the chief articles imported in 1832, were 57,500 quintals of salt fish, 86,400 hides, 75,000 lbs. cochineal, 10,600 bales cotton, 15,600 boxes, 35,300 bags sugar, 16,200 pigs of lead. The late removal of the interior customs duties will be favourable to her improvement.

2708. *Savoy* is a province of considerable extent, which in its surface and aspect is much more analogous to Switzerland than to Italy: it consists of rugged rocks, and mountains rising into the regions of perpetual snow; interspersed, however, with a number of fertile and agreeable valleys. Some of the principal passes over the Alps into Italy are through Savoy, which till lately was the only one from France or Switzerland that was passable for carriages. The Little St. Bernard, by which Hannibal is now generally supposed to have passed, is also situated in Savoy. It was much improved by Napoleon. Many of these rocks, composed of loose limestone strata, are perpetually crumbling. In 1248, a great part of Mont Grenier, near Chambery, fell, burying a village and church, and overspreading the surface of five parishes, which are still covered with the fragments piled in small conical hillocks. Mont Blanc, the loftiest mountain in Europe, is within the limits of Savoy; but as it is approached by way of Geneva, and forms part of the most elevated range of the Alps of Switzerland, we prefer including it in the description of that country. The Savoyards are brave, industrious, poor, more social than the Swiss, though less noted for cleanliness. The towns in this elevated district are agreeable and rural, situated in its most fertile and open plains, but do not attain to much magnitude or importance. Chambery, on the high road into Italy, is an old town, somewhat gloomy, but not ugly, and in the midst of a variegated and beautiful country. Moutiers, capital of the high district of Tarentaise, and Annecy, at the extremity of a picturesque lake of the same name, are pleasantly situated, though not well built places.

2709. *The island of Sardinia* is one of the least valuable portions of the kingdom, though possessed of advantages which should render it very much the reverse: few regions exceed it in natural fertility; the surface is finely variegated with gentle hills, which only along the western coast assume the character of mountains. Grain, notwithstanding the most wretched cultivation, affords a surplus for export. The wines are reckoned equal to those of Spain, and the olives to those of Genoa and Provence. The salt-works and the tunny fishery are very important objects; and the situation of Sardinia, in the heart of the Mediterranean, and with a number of fine harbours, might afford the opportunity of an extensive commerce. Yet the population is in the most uncultivated and savage state, perhaps, of any in Europe. The peasantry in the interior are clothed, in a great measure, in shaggy goat or sheep skins; they subsist chiefly by the produce of their flocks, and by hunting; and go constantly armed, for their own defence against the numerous and desperate banditti, by whom the mountains are infested. The Sardinian government appears really to have made very extraordinary exertions for this its rude appanage. The want of roads, and the extensive commons, were considered the two chief causes which perpetuated its evils. A plan was, therefore, traced to form one great road across the kingdom from north to south, between the two leading points of Cagliari and Sassari, from which eight cross roads might branch off so as to embrace the most important points in the east and west. The principal road was begun in November, 1822, and was expected to be completed in December, 1826. Laws were also passed to authorise and encourage the division of commons. The good effects of these measures, how-

ever, are as yet only prospective. At present, Sardinia has the tunny fishery, the produce of which varies much with the state of the wind, and other circumstances. In 1816, it amounted to 17,500 fish; in 1822, to only 3500; in 1823, to 11,000; and in 1824, to 5300. Sea salt, evaporated by the heat of the sun in the shallow bays near Cagliari, Palmas, and Oristano, is employed in salting both meat and fish, and as an object of direct exportation. Grain, produced to the amount of nearly 3,000,000 bushels, was formerly the principal object of export; but its value has, of late, been greatly reduced by the competition of Odessa. The horses are of a good breed: according to M. Cibrario, 32,000 only are tame, and 20,000 wild. He gives a still more striking picture of the rude state of the country when he adds, that of the cattle, 120,000 are tame, and 350,000 wild; and that, of 840,000 sheep, the whole belong to the latter class. There is, however, a considerable export of salted meat and cheese. About a third of the surface consists of forest, a considerable portion of which is oak, and well adapted for shipbuilding. Cagliari and Sassari are both considerable cities; the former having a considerable trade, but crowded, ill built, and ill paved; the latter smaller, but more elegant: both have universities, with tolerable libraries. Oristano has a fine harbour, and flourishes by the tunny fishery, and by the culture of wine in its neighbourhood.

SUBJECT. 5. *States of the Kingdom of Naples.*

2710. *The kingdom of Naples*, or, as it is called, of the Two Sicilies, is the most considerable in Italy for extent and population; in which respects it approaches to the rank of the great monarchies; but the supine and indolent character of its government almost prevents it from having any weight in the political system. Neapolis, though a place of some consequence under the Romans, was not until the middle ages a kingdom, in which the republican spirit, so active in the north of Italy, was early subdued. Naples was successively governed by branches of the house of Austria, and of the Spanish Bourbons, which last is now on the throne. On the approach of the French revolutionary army in 1795, Naples yielded without any resistance, except that spontaneously made by the despised *lazzaroni*. During the greater part of the revolutionary war, the king was supported in Sicily by a British fleet and army, and on the triumph of the allied cause, was reinstated in all his territories. With the exception of a short and abortive attempt to establish a constitutional system, the government has always been absolute; yet the people suffer less from the oppression of the crown, than from the exorbitant privileges of the nobles. The accession of Sicily, in exchange for Sardinia, effected in 1720 through Austrian influence, rendered the kingdom much more valuable and compact. These two members are, however, so very distinct, that it will be necessary to consider them separately.

2711. *Naples*, the southern extremity of Italy, after forming for some space a continuation of the long narrow peninsula which comprises most part of that country, branches finally into the two smaller peninsulas of Otranto and Calabria. The Apennines fill its interior, shooting out branches to its bounding promontories; they in many places spread wider, and assume still more rugged and awful forms than in the northern part of their line; and they harbour the most formidable troops of banditti which infest Italy. They leave, however, along the coast, wide plains and extended valleys, blessed with the most genial climate, and the richest soil of any country in Europe, or, perhaps, in the world. The culture, also, notwithstanding various administrative defects, is so diligent as to support a very numerous and very dense population.

2712. *Naples* is divided as follows:—

	Population.	Principal Towns.
Napoli	- 819,000.	Naples, 354,000. Castellamare, 15,000.
Terra di Lavoro	663,000.	Terra del Greco, 15,000. Capua, 8000. Aversa, 13,000. Gaëta, 15,000.
Principato	- 1,086,000.	Avellino, 13,000. Salerno, 11,000. Nocera, 9000.
Abruzzo	- 716,000.	Aquila, 13,000. Chieti, 11,000.
Capitanata	- 289,000.	Foggia, 21,000.
Molise	- 234,000.	Campobasso, 800.
Bari	- 375,000.	Bari, 15,000. Barletta, 17,000. Trani, 14,000.
Otranto	- 324,000.	Taranto, 18,000. Lecce, 14,000. Gallipoli, 8000. Otranto, 3000.
Calabria	- 1,433,000.	Reggio, 16,000. Catanzaro, 11,000. Cosenza, 10,000.

2713. *Naples* (*fig. 324.*) is the largest city in Italy, and fully maintains its place among the most beautiful European capitals: this is not owing to its architecture; for though the edifices are lofty and solid, the streets tolerably wide, particularly the Strada de Toledo, which is a mile in length, yet all the particular buildings are characterised by that bad taste which has always ruled at Naples, and to compensate for which, marbles, gilding, and decoration, have been vainly lavished on its churches and palaces. Taken collectively, however, Naples presents to the sea an immense line of lofty edifices, producing a general pomp of effect, and forming a commanding feature in the matchless landscape. Its bay, occupying a wide circuit of sixteen miles, every where bounded with vineyards, hills, woods, convents, villages; the golden shores of Baiæ, the beautifully variegated islands of Ischia and Procida, with the verdant sides and lofty cone of Vesuvius: all these, viewed under a brighter sun than

ever shines in the regions beyond the Alps, have been considered as composing the most splendid picture which nature presents to the human eye. The interior of Naples exhibits

324

NAPLES.

a most singular living scene; every trade and every amusement being carried on in the open air. "The crowd of London," says Forsyth, "is a double line in quick motion; it is the crowd of business. The crowd of Naples consists in a general tide rolling up and down, and in the middle of this tide an hundred eddies of men. You are stopped by a carpenter's bench, you are lost among shoemaker's stools, you dash among the pots of a macaroni stall. Every bargain sounds like a battle: the popular exhibitions are full of grotesque; they consist of Punch held as the representative of the nation; of preaching; selling Agnus Deis; dancing to the guitar; or listening to old tales." The higher classes are generally accused of licentiousness, though Eustace thinks the charge somewhat exaggerated. A very literary spirit prevails; the Neapolitans boast that as many books are published at Naples as at Paris; and that, if the world would judge impartially, they would find the one as good as the other: but this opinion does not prevail in other countries. Most ample opportunities of study are certainly afforded, by four libraries open to the public; one of which, compounded of the Farnese and other libraries transported from Rome, comprises many curious and valuable works. With these were conveyed some of the finest specimens of ancient sculpture, the Torso, the Hercules, the Urania; and some fine specimens have been appended from the greatest Italian schools; but Naples could boast no great painters of its own, and has, therefore, no frescoes of any importance. One bright redeeming quality in the Neapolitans is charity: their hospitals are numerous, richly endowed, and supported by ample benefactions; and persons of the first rank, assuming the dress of religious fraternities, not only superintend these establishments, but watch the sick-bed of the patient. The Neapolitans set an example, which seems worthy of imitation, in having a rural hospital for recovering the health of invalids. They have also *conservatorii* or schools, where the children of the lower ranks are initiated in trades, by which they may gain their subsistence. A great part of these is devoted to the teaching of music; and is unfortunately combined with that horrid mode of attaining excellence in it which is peculiar to Italy, and which, though prohibited by the government, continues still to be practised. Naples may be considered as the musical capital of Italy: the greatest composers have been its citizens; and its opera is unrivalled.

2714. *The environs of Naples* present a combination of all that is most beautiful and all that is most terrible in nature; they extend along the western shore from Naples to Miseno,

325

POSILIPPO.

which forms the termination of the bay. One of the chief ornaments is the mountain of Posilippo (*fig. 325.*), which spreads its varied outline for several miles along these enchanting shores. Its promontory is variously broken into bays, islands, and caverns; but the object which above all attracts the traveller, is the Grotto. In one of the wildest and most picturesque recesses of its romantic defiles opens this famous artificial excavation, which penetrates through the mountain for three quarters of a mile on the way to Puzzuoli. Baia, viewed by the Romans as the most enchanting spot on earth, was absolutely crowded with the villas of their great men. Here was the academy of Cicero, the favourite haunt of Virgil, the palace of Lucullus, and afterwards, unfortunately, the scene of the brutal voluptuousness of Tiberius and Nero. The lake of Avernus,

and the Elysian fields are neither so dreadful nor so beautiful as their names would import. The tomb of Virgil (*fig. 326.*), on one of the most beautiful heights of Posi-

VIRGIL'S TOMB.

lippo, excites, perhaps, stronger emotions than any other of these objects. This, however, is the subject of a serious controversy: Addison, Forsyth, and Matthews reject it as wholly apocryphal; but Eustace contends that the long and constant chain of tradition cannot be disproved by the doubtful authority which places it on the opposite side of the bay. Farther on, the village of Puzzuoli occupies the celebrated site of the ancient Puteoli, where the remains of an amphitheatre and of a temple of Jupiter almost vie with the monuments of Rome. The

WARM SPRING OF SOLFATARA.

beauty of this region, however, is gloomily mingled with the terrible indications of ancient conflagration. The Solfatara, a naked plain, surrounded by a rampart of shattered hills, is evidently heated by a subterranean fire, sensible to those who pass over it, by whom the workings of the furnace beneath are distinctly heard. When struck, it re-bellows in hollow murmurs; sulphureous exhalations rise from the crevices; and a pale blue flame is seen issuing by night from an orifice in this ever-burning plain (*fig. 327.*). The quarries of the peculiar stone called Puzzolana, which is used in several manufactures, present a striking and picturesque aspect (*fig. 328.*). The Grotto del Cane is a small aperture, whence issues a vapour so strongly impregnated with carbonic acid as to be deadly to all who breathe in it. Near it are several natural vapour baths, used with success in the cure of diseases. The

QUARRY OF PUZZOLANA.

Lucrine Lake, on which the ancients had erected several magnificent edifices, was nearly filled up in one night by the Monte Nuovo, a black mass of scorïæ and ashes, which rose suddenly from the bosom of the waters. The city of Cumæ is now a miserable village; but the celebrated grotto of the Sibyl may still be discovered, with some remains of those subterranean galleries, by which she was enabled to form the awful sounds which in the moment of inspiration issued from the depths of the cavern. Sorrento (*fig. 329.*), a little port on the extremity of the bay, is admired for its beautiful scenery, and the striking aspect of its volcanic rocks.

2715. *Vesuvius*, about eight miles from Naples, with an arm of the bay interposed, rears her majestic cone, the only volcanic mountain on the continent of Europe, and one of the most active in the world. From the earliest ages on record, its eruptions have occurred at intervals of a few years; and those of 1794 and 1822 caused a considerable dimi-

nution of its height, large portions from the sides of the crater having fallen in. On these occasions the lava issues forth in vast streams, overspreading the country for miles, and burying even cities. The town of Torre del Greco was overwhelmed in 1794; but the most memorable catastrophe of this nature was that which, in the first century, befell the two cities of Herculaneum and Pompeii, which were completely buried beneath torrents of lava. They remained entombed for ages, till the beginning of the last century, when a peasant, in digging a well, discovered some fragments of marble, and by degrees a small temple, and some statues; but this observation was neglected till the king, in 1736, designing to erect a palace at Portici, purchased the ground, and began to make large excavations, in consequence of which the entire subterranean city appeared beneath (*fig. 330.*). Numerous paintings, in perfect preservation, and manuscripts written on papyrus, have been found

329

SORRENTO.

amid the ruins. The operations have been limited by the depth of the lava, and by the city of Portici being built above. About 1750, Pompeii was discovered; and being found

330

HERCULANEUM.

much more accessible, very extensive excavations have been effected, particularly by the French; and travelers may now walk through a great extent of the ancient Pompeii (*fig. 331.*). It exhibits the full picture of what a Roman city was: habitations, temples, theatres, baths, the shops of the different trades, the implements they used, and even the materials on which they were employed.

2716. *Salerno* (*fig. 332.*), on the opposite side of the bay, is a pretty large town, in a beautiful and fertile territory, enclosed by ranges of

331

ENTRANCE TO THE PRINCIPAL STREET OF POMPEII.

lofty mountains. Considerably to the south, on a plain near the sea, appear the remains of Pæstum, the ancient capital of Lucania. They consist of three temples, which form perhaps the purest and most perfect specimen extant of the Grecian Doric order. They stand solitary near the sea-shore, without the least remains of Posidonium, the city to which they belonged.

2717. The northern part of Naples is divided between the Campagna Felice of the ancients, now Terra di Lavoro, and the rough mountain territory of the Abruzzo, the ancient Samnium. Campania is still both fruitful and highly cultivated, though it no longer produces

332

SALERNO.

the Falernian wine, so boasted of by the voluptuous poets of Rome. Capua, which almost disputed the title of capital of Italy, and whose voluptuous pleasures ruined the army of Hannibal, after it had vanquished all the armies of Rome, is now only a consider-

able but dirty town, with a strong castle. Gaëta has derived great importance from its position on an almost peninsular neck of land, the approaches to which are so strongly fortified, as to render it almost impregnable. Benevento, a town of ancient celebrity, afterwards the seat of a Lombard dukedom, which extended over almost all Naples, is filled with monuments interesting to the antiquary. The people of the Abruzzi, higher and lower, the descendants of the ancient Samnites, who made such a formidable resistance to Rome, and repeatedly sent her armies under the yoke, are still a brave and laborious race. The capitals, Aquila and Chieti, are considerable country towns, without any thing remarkable. Foggia, in Capitanata, is a considerable market for wool and corn, which are exported at Manfredonia. In the southern provinces, the mountains take an easterly direction towards Calabria, and have between them and the Adriatic the plains bearing the classic appellation of Magna Græcia. This region, once the combined seat of learning,

greatness, and voluptuous effeminacy, is now almost unknown to the rest of Europe. Yet the scenery possesses a softness and beauty, mingled with grandeur, that is scarcely equalled elsewhere; and the towns, though they cannot be compared with the great capitals of Italy, present striking and interesting monuments. Tarento (*fig. 333.*), once

TARENTO.

rival to Rome, is still a considerable sea-port. Brindisi retains only a small remnant of the importance which it derived from being the port of passage from Italy into Greece.

334

GROTTOES OF POLIGNANO.

Bari and Barletta are modern and rather handsome and flourishing sea-ports. Polignano, to the south of Bari, is also considerable, and its vicinity is marked by some very singular and beautiful grottoes (*fig. 334.*). Gallipoli is the chief mart of the oil produced in this region, which is esteemed above every other for the manufacture of fine woollen cloth. Corigliano (*fig. 335.*), nearly on the site of Sybaris, presents an aspect strikingly picturesque. The plain of Sybaris, behind it, the

abode of a people noted for voluptuous indulgence, appears, by the description and delineation of St. Non, to be of almost unrivalled beauty.

CORIGLIANO.

It is diversified with rich groves of orange and citron, above which rise finely cultivated hills; while the distance is formed by the mountains of Calabria, capped with almost perpetual snow (*fig. 336.*).

2718. Otranto (*fig. 337.*), the ancient Hydruntum, is a small town, distinguished only by its spacious castle, which has been celebrated even in romance.

2719. Calabria, on the opposite side of this southern extremity of Italy, is a striking and singular

region. The Apennines here tower to a stupendous height, and leave between them and the sea only a narrow but extremely fertile plain. The inhabitants bear in a great

336

PLAIN OF SYBARIS.

measure the character of mountaineers: they are poor, brave, rude, and almost bandit. They are often in opposition to the government in its attempts to maintain order and peace; yet, when they saw it invaded, and even conquered, by a foreign enemy, they opposed

337

OTRANTO.

a formidable resistance, after all the regular troops and ordinary resources had failed. Calabria possesses a fatal distinction, in having exhibited the phenomena of earthquake on a more terrible scale than in any other part of Europe, or perhaps of the old world. During successive weeks the whole ground heaved with a perpetual agitation: hills were levelled, and plains raised into hills; lakes were filled up, and new ones formed. An unfortunate party, which sought refuge on the sea-shore, were overwhelmed, in consequence of the sudden

SQUILLACE.

partial fall of a high mountain. Reggio, the ancient capital of the Rhegians, situated almost directly opposite to Messina, presents interesting remains of antiquity, and derives also a considerable animation from modern commerce. Squillace (*fig. 338.*) is antique and picturesque; but Catanzaro is the largest town in Calabria, and possesses some manufacturing industry.

2720. *Sicily*, the finest and most beautiful island in Europe, forms a valuable appanage to the kingdom of Naples. From the south-eastern extremity of Italy, this island extends eastward in an irregular triangle, about 180 miles long and 150 broad. Immediately beyond the narrow strait which separates it from the continent, the surface begins to rise into the lofty heights of Etna, a mountain higher than any of the Apennines, and which strikes admiration and terror by the streams of volcanic fire which issue from it. Its branches overspread nearly the whole island, but on the northern and southern coasts they descend into gentle and cultivated hills. From these elevated regions descend numerous and rapid streams, which profusely water every part of the territory. Sicily possesses thus all the beauties and benefits of a warm climate, without even the partial aridity to which it is exposed. Its soil yields abundantly all the products of the finest temperate and even tropical climates. Its most uncultivated spots are covered with groves of fruit trees, and decked with beautiful flowers, such as elsewhere are carefully reared in gardens.

2721. *In its historical character*, Sicily possessed anciently the highest distinction; and perhaps no country in the world has suffered a greater reverse. Greece early established here the most flourishing of her colonies; Syracuse and Agrigentum vied in power, learning, and wealth, with the mother country. Even when no longer able to maintain her own independence, she became the brightest prize for which Carthaginian and Roman contended. Reduced finally under the Roman empire, Sicily became one of its most valuable provinces, and the granary of the capital. In the early part of the middle ages, the Saracens founded here a flourishing state. After the establishment, however, of the Norman adventurers in the south of Italy, Roger, brother to Robert Guiscard, by a series of gallant exploits, drove out that powerful people. Sicily was then united with Naples, to which it has generally continued attached, though held occasionally by Spain and Savoy. It was also separated for a considerable time, when the French became masters of Naples, while the old family were maintained in Sicily by British protection; but on the fall of Murat, in 1815, the Two Sicilies became again one kingdom.

2722. *Sicily at present*, notwithstanding its fertility and varied natural advantages, has sunk into a state of extreme poverty and degradation. The supineness and tyranny of the government, and the exorbitant privileges of the grandees, have reduced the body of the

people to a state of the utmost penury. The varied and often rugged surface of the country, intersected by numerous torrents, would require considerable efforts to form communication by roads; but this has been entirely neglected, and a line of twenty miles into the interior from Palermo is the only route practicable for carriages. In Agrigento, once the mart of all the commodities of the Mediterranean, M. Kephallides could not procure a pair of gloves; and in Modica, a town of 11,000 people, a bit of soap was not to be obtained. Sicily, however, produces some wines that are esteemed; her raw silk is also fine, and with olive-oil, fruits, and salt, affords some materials for exportation. In return, she receives manufactured goods in great variety, though small quantity, their consumption being much limited by the poverty which pervades the great body of the people.

2723. *Sicily* is divided into the following intendantscies:—

	Population.	Principal Towns.
Palermo	409,000	Palermo, 168,000.
Trapani	147,000	Trapani, 24,000. Marsala, 21,000.
Girgenti	291,000	Girgenti, 15,000.
Caltanissetta	156,000	Caltanissetta, 17,000.
Syracuse	194,500	Syracuse, 15,000.
Catania	292,500	Catania, 45,000.
Messina	240,000	Messina, 60,000.

2724. *Palermo*, though it can boast neither monuments of antiquity nor classic modern edifices, such as adorn the cities of Italy, is yet a spacious and handsome city. It is traversed by broad streets crossing each other, and producing at their point of junction a striking effect. Many of the quarters, however, are ugly and dirty. The cathedral is a large ancient edifice, with some striking features; but the different styles of architecture are injudiciously blended. The palace of the viceroy is a splendid building, but not in good taste; its most interesting object is the ancient chapel of king Roger. Some of the country seats in the vicinity command delightful views. The favourite resort of the Palermitans is a public garden called the Flora, which is not well arranged, but is rich in flowers and fruit.

2725. *Messina* (fig. 339.), though smaller, is almost equal in importance, since from it is carried on almost the whole commerce of Sicily. Its wines, silk, fruits, and other articles

PORT OF MESSINA.

produced for exportation, are mostly shipped at Messina. It has also a considerable silk manufactory. The city is beautifully situated on a bay, formed by the opposite coasts of Sicily and Calabria, and enclosed by lofty hills on each side. A century ago, Messina was much greater, and more flourishing; but it has passed since through calamities almost unparalleled. In 1743, the plague swept off half its population; and in 1783, the great earthquake, which was desolating Calabria, crossed the strait, and in a few minutes converted Messina into a heap of ruins. Most of the inhabit-

ants effected their escape; but the finest streets were overthrown; precious commodities, libraries, works of art, were destroyed in vast numbers. From this fatal blow Messina has only imperfectly recovered.

2726. *Southward from Messina*, the coast begins to display the remains of great an-

CATANIA.

cient cities, which were built chiefly on the eastern and southern coasts. Taormina, the ancient Tauromenon, now a small place, contains, among other ruins, a theatre, considered one of the most perfect monuments of antiquity, and in a most commanding site, between the mountains and the sea. Catania (fig. 340.), at the foot of Etna, is the finest city in the island. It is filled with Greek, Saracenic, and modern structures, all handsome. Yet it has passed through fearful vicissitudes. Overwhelmed by the volcano of 1669, almost de-

stroyed by the earthquake of 1693, it has risen from these disasters with undiminished beauty.

2727. *Proceeding southward* along the coast of the Val de Noto, we reach Siragusa (Syracuse). This ancient capital, so celebrated for power, learning, and splendour, presents now a striking example of the changeful character of human things. Of its vast ruins only some imperfect fragments can with difficulty be traced, scattered amid vineyards, orchards, and cornfields. The present town, which contains nothing remarkable, occupies only a very small portion of the ancient site. Near the south-eastern cape of Passaro are Noto and Modica, two large towns, one well built, the other very indifferently.

2728. *On the southern coast*, Girgenti (*fig. 341.*), now a large poor village, presents

341

ENVIRONS OF GIRGENTI.

monuments worthy of the ancient Agrigentum, when it was the greatest city of Sicily, and fit to contend with Carthage. The temple of Jupiter Olympus (*fig. 342.*), an immense structure, 368 feet long by 188 broad, is almost quite in ruins. It has been called the Temple of Giants, from huge forms of this description that are lying either entire or in fragments. The Temple of Concord (*fig. 343.*), with its thirty-four columns, is considered one of the most perfect specimens extant of the Doric

order. Farther to the east at Selinunti, the ruins of Selinus present a scene still more striking and awful. Here may be distinctly traced three noble temples, of which the

342

TEMPLE OF GIANTS.

343

TEMPLE OF CONCORD.

materials still remain, but only a few solitary columns are standing; all the rest lie on the ground, in huge and shapeless blocks, forming the most stupendous mass of ruin to be found in Europe. It is generally supposed that an earthquake has been the cause of this extraordinary destruction, — that, as Mr. Swinburne expresses himself, nature has been chiefly concerned in this triumph over the pride of art (*fig. 344.*).

344

RUINS OF SELINUS.

2729. *Trapani*, the ancient Drepanum, poetically distinguished as the place where Anchises died, and where Æneas celebrated his obsequies, is still a considerable town, near the western promontory of Sicily, the ancient Lilybæum. It is well fortified, and has a good harbour, where there is a considerable trade in the export of salt made in its vicinity, and of barrilla. It carries on briskly the fisheries of tunny and of coral, which last is obtained both from the coast of the island and that of Africa. Not far from Trapani is Segeste; a simple, grand, and almost entire edifice, standing on a solitary hill (*fig. 345.*).

345

TEMPLE OF SEGESTE.

Marsala, almost on the very site of Lilybæum, is a considerable town, exporting wine that is much esteemed. Near it the quarries of Mazzara appear to have furnished the stone of which the edifices in this part of Sicily have been constructed.

2730. *The ascent of Etna* is a general object with Sicilian travellers. In proceeding

346

SUMMIT OF ETNA.

from Catania, they pass through three successive zones: first that of rich cultivated fields, then that of plants and aromatic shrubs; and, lastly, the region of scorix, ashes, and perpetual snow. On reaching the summit (*fig. 346.*), they view the crater filled with vast volumes of smoke, and obtain a fine panoramic view over all Sicily and the adjoining shores of Italy.

2731. *The Lipari Islands*, twelve in number, and situated from twelve to thirty-five miles northward from

the Sicilian coast, are entirely volcanic, and appear to have been thrown up from the sea by the action of fire. Lipari itself contains a hill of white pumice, which forms an article of trade, and its crater displays various specimens of beautifully crystallised sulphur. Stromboli has a volcano, remarkable for being in perpetual activity. Every day, at short intervals, the eruptions issue forth like great discharges of artillery, and the sides of the mountain are covered with the red-hot stones that are ejected, and rush down into the sea. The inhabitants of these islands are a bold, active, and industrious race. The activity of submarine fires has been manifested on another side of Sicily, by the recent rise of Graham's Island; only, indeed, a volcanic rock, which has again sunk under water.

2732. *Malta* (*fig. 347.*), an islet in the Mediterranean, about fifty-four miles to the south of Sicily, though imperfectly connected with Italy, belongs more to it than to any other

347

MALTA.

country. It obtained little notice in antiquity; and, when St. Paul was shipwrecked there, is described as inhabited by a barbarous people. Its importance began in the sixteenth century, when it was ceded by Charles V. to the Knights of St. John of Jerusalem, as a compensation for the loss of Rhodes. Its fortifications were then greatly strengthened, and it was considered the last maritime bulwark against the Turks. In 1565, Solyman sent against Malta a most formidable fleet and army; and the siege which ensued is one of the most celebrated in history. After prodigious efforts, the Ottoman armament was completely repulsed, and the knights were left in the unmolested possession of the island, till 1798. Napoleon then, with the expedition destined for Egypt, suddenly appeared before La Valetta, and took possession of it without resistance. Britain afterwards reduced it by blockade; and, notwithstanding a stipulation in the treaty of Amiens, has since retained possession of it. In 1825, the native population of Malta amounted to 99,600; the garrison and strangers to 3200. On the neighbouring smaller island of Gozo there were 16,800. The people are industrious; and, notwithstanding the barrenness of their soil, raise grain, cotton, and excellent fruits, particularly oranges.

2733. *La Valetta*, the capital and port of Malta, being situated on a narrow tongue of land, with a noble harbour on each side, forms an admirable naval station, deriving great importance from its position in the heart of the Mediterranean. It serves also, especially during war, as a commercial depôt, whence goods may be introduced into Italy and the Levant. The exports from Britain, in 1829, amounted to 505,250*l.* while the imports were only 20,780*l.*

CHAP. IX.

SWITZERLAND.

2734. *Switzerland* forms a mountainous territory in the centre of Europe, occupying the west of the great range of the Alps, which divides France and Germany from Italy. It is remarkable for the grandeur of its natural features and scenery, and for the freedom of its political institutions.

SECT. I. *General Outline and Aspect.*

2735. *Switzerland* is bounded by the great kingdoms of France, Germany, and Italy, whose frontiers enclose it on all sides; France on the east; Germany, and more particularly Swabia and the Tyrol, on the south and west; the Italian states, Milan, Piedmont and Savoy, on the

south. In general, Switzerland terminates where its mighty mountain heights slope down to the vast plains which extend over the surrounding regions; but on the side of the Tyrol on the west, and of Savoy on the south-west, the line is drawn across the crest of the Alps themselves, which stretch away with almost undiminished grandeur towards opposite seas. Its position is nearly between 46° and 48° north latitude; and 6° and 11° east longitude. It may be about 200 miles in length, and 140 in breadth, and comprises an area of 19,000 square miles.

2736. *The surface* of Switzerland, bounded and traversed as it is by the highest ranges in Europe, consists almost wholly of mountains and lakes. The Alpine chains, however, do not swell, like those of America and Asia, into mighty and continuous table-lands; they are separated by deep valleys or narrow plains, which form the basin of large rivers, or the bed of extensive lakes; hence arises a singular variety of climate and aspect; for while the valleys beneath are scorched by the intensest rays of the sun, perpetual winter reigns in the heights above, and the vegetation of the arctic circle passes into the snows of the polar world.

2737. *Of the mountains* of Switzerland, Mont Blanc stands at the head; being the loftiest in Europe, and supposed, before the late observations on those of Asia, to surpass all the heights of the old continent.

2738. *Mont Blanc* is within the limits of Savoy; but forming, as it were, the key of the great Alpine chain, and all its approaches being on the side of Switzerland, it has always been regarded by Europeans as decidedly Swiss. The scenery to the west of Mont Blanc, in the approach from Geneva, presents the most striking display that is to be found in Europe, of whatever is wild, wonderful, and sublime in Alpine scenery. The Valley of Chamouni, the Glacier of Bossons, and the *Mer de Glace*, present, in particular, scenes of the most astonishing grandeur. The upper regions of the mountain were long considered as inaccessible to the foot of mortals; but Saussure first, and several English travellers since, have, by fearless enterprise and adventure, succeeded in penetrating across the steep slopes covered with ice and snow, the perilous chasms, the narrow and slippery paths along precipices, and all the other dangers which beset this daring ascent. North-east from Mont Blanc extends the line of those amazing Alps which form the Italian boundary: the Great St. Bernard; Monte Rosa, which ranks second in height to Mont Blanc; the Simplon, across which such an astonishing military road has been excavated; Mount St. Gothard, the route over which, however rugged and dreary, was, previous to the formation of that of the Simplon, the most frequented of any from Switzerland into Italy. Beneath this range extends the deep valley of the Rhone, from the northern side of which again shoots up another series of peaks, or horns, as they are here termed, which, though they nowhere attain the unrivalled height of Mont Blanc, present a more continuous elevation, and a more imposing mass, than even those which border on Italy. Among these peaks, the most memorable are the Schreckhorn or Peak of Terror, the Wetterhorn or Peak of Storms, the Gletscherhorn or Glacier Peak; and, peering above all, the Finster-Aar-horn, which ranks third in height after Mont Blanc and Monte Rosa. Down the prodigious steep slopes which these present to the plain of Berne, descend the glaciers, or great fields and plains of ice, which, sliding down from the upper region of the mountains, reach the lower valleys, where they remain unmelted, and even accumulate in successive seasons, and are often seen bordering on the cornfields and vineyards. The whole of southern Switzerland is covered by these great ranges; but the northern part presents a somewhat different aspect. In the east, the territory of the Four Cantons is diversified, indeed, by several very high and picturesque single peaks, as Mount Righi and Mount Pilate; but the general ranges which enclose its lake vary from 2000 to 4000 feet. The north-west district, consisting of the canton of Friburg, with great part of those of Berne and Soleure, composes an extensive plain, the only one which exists in Switzerland, and from which the mountains are only seen in white and distant lines; but the whole frontier of this side towards France is barred by the steep though not very lofty ridge of the Jura.

2739. *The great rivers* which water the surrounding regions either take their rise in Switzerland, or are swelled by tributaries from that country. The Rhine and the Rhone have both a long course, and have risen to streams of the first magnitude before they pass its frontier. These, with the Aar, the Reuss, and the Tesino, rise from the vicinity of each other, where the two great chains nearly unite, and where the Schreckhorn, the Finster-Aar-horn, and St. Gothard tower above the wild valleys of Urseren and the Upper Valais.

2740. *The Rhone* flows through the deep valley between the Italian chain and that of the central peaks, and is swelled at every step by numberless torrents dashing down their sides. At length, emerging from this mountain region, it diffuses the huge mass of waters thus collected into the ample expanse of the Lake of Geneva. At the opposite extremity, near the city of that name, it bursts out, and rolling towards the frontier, becomes finally a French river. The Rhine has its first course along the most obscure Grison and Tyrolean frontiers, but on touching the German plain it spreads into the wide and beautiful Lake of Constance. Thence emerging, it flows nearly due east, forming the almost continuous northern boundary of Switzerland on the side of Germany; till, at Basle coming into contact with France, it strikes suddenly to the north, and bids a final adieu to its parent country. The Aar, the only large river exclusively Swiss, descends from the Finster-Aar-horn, rolls along the foot of the glaciers, collecting all their waters, which it distributes among the lakes of Thun and Brienz; after which it passes by a circuitous course along the level tracts of Switzerland, till it joins the Rhine on the German frontier. Almost immediately before this junction, it has received the Reuss (fig. 348.), from a source in the heart of the wildest scenery of St. Gothard, and which in its northern course has formed the great Lake of the Forest Cantons. The Limmat, also, after forming the Lake of Zurich, enters nearly at the same point. To the Danube Switzerland also contributes the Inn, through the valley of Engadine, while it gives to the Po the Adda from the Valteline, and the Ticino from the heights of St. Gothard.

2741. *Lakes* form a conspicuous feature in the physical structure and scenery of Switzerland. Its rivers, after rolling for a considerable space through mighty mountain valleys, accumulate a mass of

SOURCE OF THE REUSS.

waters which, when they reach the plains, no longer find a channel capable of containing them, but spread into wide watery expanses. The lakes of Switzerland are large, though none of them have that vast extent which could entitle them to be classed as inland seas. The smiling valleys and cultivated hills which form their immediate border, with the mighty mountains which tower behind in successive ranges, till they terminate in icy pinnacles rising above the clouds, produce a union of the sublime and beautiful which no other part of Europe, or perhaps of the world, can rival.

2742. *The Lake of Geneva*, or *Leman Lake*, is the most extensive, being about fifty miles in length, and twelve in its greatest breadth. The varied beauties of its northern bank, the opposite heights of Meillerie, and Mont Blanc rising behind in the distance, render it perhaps the most beautiful lake in the world. The Lake of Lucerne, or of the Four Forest Cantons, has, from its winding form, and the great variety of its scenery, sometimes been considered as superior. The Lake of Zurich does not offer the same sublime beauties; but the gentle elevations by which it is diversified form many scenes of extreme beauty. That of Constance has none of the mountain grandeur of interior Switzerland, but its extended banks present many pleasing cultivated and pastoral scenes. The southern lakes, Maggiore, Como, Lugano, which half belong to Italy, exhibit many magical scenes, combining the gay splendour of the Italian plain with the grandeur of its mountain boundary; yet they do not possess that deep stillness and solemnity which gives a peculiar charm to the lakes that are entirely enclosed within the Alpine barrier.

SECT. II. *Natural Geography.*SUBSECT. 1. *Geology.*

2743. *The geognosy* of this magnificent country, although it has engaged the attention of geologists from the time of Saussure up to the present period, is far from being well understood. We cannot here enter into the discussions connected with the age, characters, and distributions of its formations, which now occupy the talents of so many distinguished observers; but refer our readers to the writings of Saussure, Ebel, Escher, Von Buch, Necker, Boué, Kefferstein, Brongniart, Murchison, Buckland, Sedgwick, Brochant, Hugi, Studer, and others. Switzerland is principally composed of Neptunian deposits; the Plutonian rocks occupying a comparatively small portion of the country.

2744. I. *Primitive and transition rocks.* (1.) *Neptunian.* These form the more central part of the country, and consist of the following rocks:—1. *Gneiss.* 2. *Mica slate.* Where the mica disappears, *quartz rock* is formed, which sometimes occurs in beds of considerable magnitude. When the quartz of the mica slate disappears, there is formed a slaty rock entirely composed of minute scales of mica, forming the *primitive clay slate* of authors. 3. *Talc slate.* This rock, which is a slaty compound of quartz and scales of talc, was long confounded with mica slate. Sometimes the quartz disappears, when a talcy rock with slaty structure is formed, known under the name *slaty talc*; which passes into the rock named *potstone*, and also into another well-known magnesian or talcy rock, named *chlorite slate*. But by far the most interesting of the rocks of this deposit is that named *protogine*, which is a slaty or granular compound of quartz, talc, and felspar. The granular varieties have been described as granite; the slaty as gneiss, or under the name *veined granite*. Nearly the whole of Mont Blanc, as far as visible to the eye, is composed of protogine. 4. *Limestone.* Beds of this rock occur in the preceding rock, and especially in the talc slate. The limestones in the latter rock are frequently *dolomites* or magnesian limestones, and afford marbles valued by the statuary. *Gypsum* and *Karstenite* also occur in the talc slate districts. 5. *Hornblende rock.* Of this rock, the principal varieties, namely, hornblende rock properly so called, and also *hornblende slate*, occur in the gneiss, mica slate, and talc slate mountains. (2.) *Plutonian rocks.* True Plutonian, or ignigenous primitive and transition rocks, are not very abundant any where in Switzerland. The following are particularly noticed by authors: *granite*, *syenite*, and *porphyry*; which latter contains quartz, and seems to be a mere modification of granite. These rocks appear to have given the Neptunian strata not only their inclined position, but also to have fractured, contorted, and variously altered their individual characters.

2745. II. *Secondary deposits.* (1.) *Neptunian.* These are disposed in the following order: the lowest or oldest is, 1. *Red marl, sandstone, gypsum, &c.*, containing occasionally large subordinate masses of *magnesian limestone*. This deposit some consider to be equivalent to the *red marl* and *keuper*. 2. *Inferior or older Alpine limestone.* This, from its organic remains, is considered as representing in Switzerland the *lias* of English geologists. 3. *Alpine limestone, with subordinate saliferous beds.* This deposit is considered as a portion of the oolite limestone, not far from the Oxford and Kimmeridge clay. 4. *Newer Alpine limestone.* Under this head are included those portions of the oolite series higher in the order than that just mentioned, and which therefore rests upon it. 5. *Green sand and chalk.* Resting upon the newer Alpine limestone there are beds of *green sand*, and of a rock which contains fossils identical with those found in *chalk*: hence it is by geologists considered as belonging to that formation. (2.) *Plutonian rocks.* The principal Plutonian rock is a *porphyry* without quartz, named *melaphire*; also *augite porphyry* and *black porphyry*. It is observed rising among the secondary deposits, and is viewed as the agent to which the strata owe their highly inclined position, and the mountain ranges their present situation. *Serpentine* and *dolerite*, also ignigenous rocks, occur among the secondary strata.

2746. III. *Tertiary deposits.* In the great valley on the north side of the Alps, which separates them from the Jura chain, there is a vast deposit of tertiary rocks, of which one of the most prominent kinds is the conglomerate named *molasse*.

2747. IV. *Alluvial deposits.* The older diluvium, which contains remains of extinct quadrupeds, as the elephant, &c., is abundant. The numerous rolled blocks of rock scattered over the country, far distant from their native places, and which appear to owe their distribution to the upraising of the mountains, are well known to travellers and geologists.

Ilanz and Truns }
Ilanz.
Truns - - - 2400

2748. This may well be called a land of mountains; consequently, its vegetation partakes very much of the alpine or arctic character; but as a great portion of its valleys resembles the climate of Italy, on the one hand, (even producing, in the warmer valleys, and in a state that may be reckoned completely naturalised, the Cactus Opuntia (*fig. 350.*), or Small Indian or Prickly Fig,) and the climate of France and Germany, on the other; so does the nature of its vegetation vary in consequence, and the flora is extremely rich and beautiful. To afford any thing like a correct idea of this, is far from our object; we must content ourselves, in this place, with giving an account of the cultivated and most striking of the spontaneous vegetation, according to its elevation above the level of the sea; and this we are aided in doing, by an interesting statement, which appeared in an early number of Black and Young's *Foreign Review*, "upon the state of cultivated and spontaneous vegetation in the higher parts of Switzerland." The elevation above the level of the sea is given in French feet: —

Buckwheat (*fig. 351.*), sown after Rye is reaped, ripens; at Ilanz it does not come to maturity; and a little higher the forty-days Maize (*quarantino*), a variety of the Zea Mays, is very precarious: at the same height, in the valley of the Upper Rhine, the vegetation of this plant ceases altogether. At this place, near the borders of Lombardy, is the limit of the cultivation of the White Mulberry; at a greater elevation, neither this tree nor silk-worms are seen. The last Walnut trees (*fig. 352.*) are seen: it is remarked that this tree thrives better in valleys with an east exposure, than in those with a north, even though elevation and other circumstances are the same.

351

BUCKWHEAT.

352

WALNUT.

Santa Maria - - - 2750.
Porta - - - 2810.

Churwalden - - - 3800.

Vilo - - - 3800.

The growth of Chestnut trees ceases near this place. The limit between the vegetation of the northern and southern districts is generally fixed here: a little higher, towards Bergonovo, a few straggling and stunted Walnut trees are seen, while at the base of the rock whereon the ancient and lofty town of Porta is built, Walnut and Chestnut trees flourish in luxuriant fruitfulness; and at a short distance from Porta, the Fig adorns and enriches the gardens, and the flanks of the mountains are clothed with the Cytisus and Broom. Here Flax, Hemp, and Barley are grown with success; Winter-Rye is not so certain a crop. Cherries ripen, but fruit with pips (*Apples, Pears, &c.*) is not grown. At Parpau, a village 600 or 700 feet higher than Churwalden, the inhabitants do not cultivate any species of grain: many kinds of trees, as the Italian Poplar (*fig. 353.*), Ash, and Wild Cherry, which grow at Churwalden, will not vegetate at Parpau; the only cultivated herb at this latter place is a variety of the Rumex alpinus, or Sorrel. Different kinds of Firs compose the entire and exclusive vegetation. A little lower, Larches, intermixed with some of the Pinus Cembra (*fig. 354.*), or Siberian Pine, commonly called Alvier, are seen: all the more common species of grain are sown, and Potatoes generally diffused. Maize, which

Place.

Elevation.

Isola - - - 3900.

Wiesen - - - 4400.

succeeds perfectly a little lower, ripens here also in ordinary seasons. In another part, however, our author seems to fix an elevation of 2000 or 2500 feet as the boundary of the productive cultivation of Maize. He also remarks, that a height of 3000 feet, with a southern exposure, will allow the cultivation of Buckwheat (*blé sarrasin*), even after the Winter-Rye has been reaped. It will be curious, and may be instructive, to compare the limit, in point of elevation, that bounds the profitable growth of maize in this part of Switzerland, with the limit, in respect to latitude, that arrests its profitable culture in France. According to A. Young, the line of separation between maize and no maize is first seen on the western side of the kingdom, in going from the Angoumois, and entering Poitou at Vêrac, near Ruffec: in crossing Lorraine, it is first met with between Nancy and Luneville: in passing from Alsace to Auvergne, the limit is at Dijon. Hence it appears that the boundary of the maize culture is two degrees and a half farther north on the eastern than on the western side of France; the northern boundary on the west side being about 46½ degrees, and on the east side about 49 degrees. From this fact, connected with the two other facts, that the northern limits of the vine and olive culture in France are parallel to the northern limit of the maize culture, Mr. Young inferred that the eastern districts of France are 2½ degrees of latitude hotter (or, if not hotter, more friendly to vegetation) than the western.

Potatoes are fit to be taken up, and Barley to be reaped, here, a month earlier than in the Oberland, where the elevation is only 3400 feet, but where there is a northern exposure. Flax and Hemp succeed here; and in the small sheltered enclosures the Sunflower expands in all its magnificence, while in the meadows the Maple and Ash exhibit every symptom of healthy and luxuriant vegetation. Our author justly remarks, that the ripening of the seeds of trees is a surer criterion of the comparative temperature of different situations and climates, than the maturing of grain or cultivated vegetables; since the perfection of these must often depend on fortuitous circumstances; as on the skill, labour, manure, &c. bestowed on them.

Near this village, on the declivity of a mountain facing south, Rye sometimes arrives at maturity, provided it is sown immediately after harvest, and Hemp not unfrequently succeeds.

353

ITALIAN POPLAR.

354

SIBERIAN PINE.

Place.	Elevation.	
Zernetz.	4400.	The inhabitants obtain a crop of Rye; but, in order to succeed, it must be sown in a particular manner; viz., in the spring, along with March Barley: after this is reaped, the rye is mown, and at the next harvest of the barley it also has reached maturity: the rye is occasionally sown with peas instead of barley. Potatoes were not tried till after the scarcity in 1817: they grow well: Hemp also thrives; but Flax, being more delicate and susceptible of cold, is not cultivated at Zernetz.
Casaccia	4600.	On the higher grounds in this neighbourhood the Pinaster or Cluster Pine tree prevails, the Larch being seldom seen, though this and the Siberian Pine constitute the chief part of the forests of the Higher Engadine. At a lower elevation, the Service tree flourishes; and lower still, near Casaccia, the Alder (<i>Betula Alnus viridis</i>) covers the side of the mountain. No description of Corn is grown. Our author observed a small patch of Potatoes, which seemed planted solely as an experiment, and did not appear as if they would ever come to perfection.
Selva	4900.	The stalk as well as seed of Flax attains perfection here. Hemp, also, has occasionally succeeded. Between 100 and 150 feet higher up, that is, at an elevation of more than 5000 feet, Barley ripens on the sides of the mountains exposed to the sun. Some Cherry trees grow at Selva, and occasionally ripen their fruit.
Valley of Au	5270.	In the inn garden were Carrots, Cauliflower, Radishes, a kind of Turnip with a carrot root, long, thin, and poor; and the White Cabbage; the last, however, not well hearted. Potatoes are not grown.
Samaden	5300.	Radishes succeed here, as well as Turnips. Potatoes do not. At 100 feet higher, towards Celerina, Barley and Oats ripen. This fact excites the author's surprise; but he does not account for it. He informs us that, in the upper district of Berne, neither one nor other of these grains will grow at a higher situation than 4000 feet; and that in a Bernese valley, with only 3400 feet of elevation, the Turnips sown in spring perish with cold; whereas the Navets d'hiver (a species of Rape?) do not suffer, and yield abundance of oil.
St. Maurice	5500.	In the kitchen-garden grow the Turnip-rooted Cabbage, Carrots, Radishes, Lettuces, and Cabbages, very indifferently hearted: the Pease were in flower.
Scarla	5580.	Notwithstanding this great height, a considerable quantity of Corn is cultivated: barley alone proves very successful; and often the premature frosts of August and September destroy it.
Campfer,	between 5600. and 5700.	Barley and Potatoes sometimes come to perfection in this district. Our author regards this as the limit of their vegetation. Trefoil will not grow higher than at Lutz, 5300 feet; and in 1822, there was no barley harvest higher than Celerina.
Sertig	5650.	Near the church of this place a few Raves were growing; but no Potatoes nor Grain. About 200 feet lower, in a sheltered situation, is a forest of Firs. Potatoes and barley often attain maturity here. In consequence of the northerly exposure of the ground near the church, Carrots will not grow, though they thrive in a loftier situation than where potatoes and barley usually ripen. At the same height, and with the same exposure, Melilot (a species of <i>Trefoil</i>) flourishes. As this plant is indigenous to Libya, and yet thrives in the cold climate of the Alps, it suggests the idea that it might be practicable to enrich the mountains of Switzerland with the native productions of warmer climes, especially among the Papilionaceous tribes. The plant in question (<i>Libyan Trefoil</i> or <i>Melilot</i>) growing at the foot of the Glaciers of Scalitta, and the Apricot tree acclimated in the Grindenwald, an elevation of 3180 feet, would seem to justify his suggestions and hopes.
Maloya	5730.	No Grain, Flax, or pot-herbs will grow here.
Splugen	5830.	The elevation of the hospice on this mountain is equal to that of the hospice on the Grimsel in Oberland; but vegetation is here far more varied and luxuriant.
Tchugen	5900.	At this high elevation the only plant cultivated is the <i>Rumex alpinus</i> , a species of Sorrel much grown in these mountain districts, for fattening swine in winter. The roots are prepared by twisting them till the cellular tissue is detached: then they are put, with a small quantity of salt, into a trench, lined and covered with planks, over which stones are placed. About 300 feet lower, the Siberian Pine and Larch present a healthy and vigorous appearance; the seed of the former ripening early in October. This tree, the <i>Pinus Cembra</i> , or Siberian Pine, is one of the most useful in Switzerland, though its growth is so slow, that one of them, about 19 inches in diameter, presented, when cut down, 353 concentric circles. Its usual increase of height is a span in six years. The timber of this tree has a most agreeable perfume, and is much employed for domestic purposes, as well as for wainscoting rooms. When our author visited the château of Tarasp, he was struck, in almost every apartment, with the scent of this wood; and he remarks it as a singular and inexplicable circumstance, that it should have thus exhaled its fragrance for some centuries in undiminished strength, and without the wood itself having suffered any decrease of weight. This timber possesses the additional recommendation that its perfume is an effectual preservative against bugs or moths. The seeds of the Siberian Pine are esteemed a delicacy, and eaten in great quantities during the winter festivals: yet this use of them is considered pernicious to health, and the writer rather recommends applying them to the same purpose as in Siberia, where, according to Pallas, a valuable oil is extracted from them, which is eaten at table, and might be employed in manufacturing soap. This species of pine is unfortunately becoming very scarce, and its cultivation is therefore strongly recommended. In order to secure and expedite its growth, and thus remove the principal objection to its culture, it would be desirable that the seeds were deposited in a compost made of earth and the clippings and leaves of the pinaster or larch, or that this compost be laid round the roots of the young plants. The Larch is also a valuable tree to Switzerland; not only for the purpose of affording manure, but because of its durable timber. This lasts four times longer than common pine timber grown at an equal elevation. If, therefore, the larch be planted where the common pine now grows, it is evident that much of the forest ground might be gained, and applied to pasture. The foliage of the larch, Siberian pine, and several other

Place.

Elevation.

Berenboden - 6225.

trees, is carefully collected by the Swiss peasantry on the mountains, being put into large bags for winter fodder, and then hurled downwards into the valleys below. Near Seldun, the leaves of Nut and Elm are used in a particular manner: being gathered in their prime, they are dried, and ground to powder, and in this state given to swine, mixed with their customary drink in winter; and our author was assured that this diet fattened the animals as well as barleymeal; an assertion that sounds almost incredible to British ears! In the Oberland, the bark of the young Oak, peeled off in the spring, dried and ground, is found to be equally healthy and nourishing for all kinds of cattle. A knowledge of these facts may prove useful, as affording hints for the owners of property in the mountainous districts of Scotland. For the same reason, we relate the following application of Sage (*Salvia glutinosa*) in the Oberland: they spread the stalks of this plant under the beds, or draw a broom, made of them, gently and slowly along the floor: by this means the unpleasant insects that sometimes harbour in such situations are destroyed, as they get fastened to the glutinous surface of the plant.

7400.

Though neither the soil nor exposure were favourable, Larches, a foot and half in diameter, and sixty feet high, grew here; the Siberian Pine and common Fir also flourished; 600 feet higher, some of these trees were seen growing on the top of a rock, probably the loftiest spot at which they will vegetate. Neither the Alpine Pine nor Aquatic Alder were to be found here; only some wild Medlar trees. None of these, with the exception of the larch, appeared degenerated; while on the mountains of Berne, forest trees grow stunted; and perish gradually, in proportion to the height at which they are found.

At the highest point of the Pass of Fluella, forest vegetation had ceased. Abundance of *Poa alpina*, however, was growing; and this is invaluable in a country where, owing to the mountainous nature of the pastures, the crop of fodder is always small and precarious, and every blade of grass has to be collected with the utmost care. It is common to plant those kinds of trees, whose foliage and young branches afford the most nourishing food. In places inaccessible to cattle, the Swiss peasants may be sometimes seen making hay with crampons (hooks to prevent them from falling) on their feet.

2749. The grass is cut, not three inches high, in some places three times a year, and in the valleys the fields are as close shaven as a bowling-green, all the inequalities being cut as with a pair of scissors. In Switzerland, as in Norway, for the same reason, the art of making hay seems to be carried to its highest state of perfection. In Iceland, the poor people are often seen on their knees scooping out the grass with a clasp-knife, from between the interstices of the rocks. A little below the highest point of the Pass of Fluella, in a southern aspect, the first Firs, mixed with Juniper plants, were to be seen; whereas, on the northern side, only Azaleas grew, whose rusty-coloured foliage indicated the extreme severity of the climate.

ALP ROSE.

2750. The distance which usually intervenes on the Alps between the growth of trees and the limits of perpetual snow, is 2700 feet; the tree that is found nearest the snow being the *Pinus Abies*, or Spruce Fir. The *Ericineæ* and *Rhododendron ferrugineum* (fig. 355.), commonly called the Alp Rose, do not attain a greater height than 7020 feet, and the distance between the snow and the culture of corn is 4200 feet. Plantations on mountains in England seldom succeed at a greater elevation than 1200 feet.

SUBJECT. 3. Zoology.

2751. The zoology of Switzerland participates in the singularity of its geographic features, and exhibits several native animals designed by Providence to live only in the wild recesses of mountainous districts. Among these, the

356

IBEX.

Ibex (*Capra Ibex*) (fig. 356.) is the most singular, and deserves particular notice. Although not much larger than a domestic goat, its horns are enormous, measuring sometimes two feet and a half long; and are so formidably robust, that the observer wonders how an animal apparently so heavily encumbered, can at the same time be possessed of such surprising activity. Around these horns are cross ridges, or knots, the number of which generally indicates the age of the animal. The Swiss hunters assert that the horns do not reach their full size until the twelfth year. The Ibex dwells only among the highest and most inaccessible precipices of the Alps, particularly those of

the Tyrol, and appears to delight in frequenting the frightful regions of eternal snow; yet even here they are pursued by their adventurous hunters; and their numbers both in Savoy and Switzerland are much diminishing, while they are almost extinct in the Pyrenees. The chamois, somewhat less wild, yet apparently formed for more activity, inhabits the same mountainous ridges. The descent of the domestic goat from the Ibex has been asserted with too much confidence: it rests, like many other similar questions, on mere supposition.

2752. *The Alpine Marmot* (*Arctomys marmotta*) is another of the most remarkable European quadrupeds. Although thick and ungraceful in appearance, it is endowed with surprising instinct. These animals live among the mountains in families, and form under-ground burrows; when they quit these retreats for procuring food, one of the number, as a guard, ascends an elevated spot near their common habitation. If this sentinel observes an enemy, or any unusual object, he utters a shrill cry, upon which the whole company run to their retreat; or, if too far, instantly seek a hiding-place in an adjacent cleft or hole. Such and so various are the modes by which Almighty Providence enables its weakest creatures to guard against dangers they are otherwise unable to escape from. These marmots pass the whole winter in a deep lethargy, during which time they take no nourishment. The fur is thick, warm, and well known as a valuable article of dress. The wolves of the Alps are both numerous and formidable, and the foxes live undisturbed by the huntsman.

2753. *The ornithology of Switzerland* has received much attention from the naturalists of Geneva; among whom Professor Bonelli is most celebrated. The large vultures of Germany are occasionally seen; but there is another, called the Bearded Vulture, or Vulture of the Alps (*fig. 357.*), more peculiar to this country. It is a noble bird, partaking more of the

courage and sanguinary nature of the true falcons, than of the vultures, to which group, from the structure of the bill, it nevertheless more strictly belongs. Its length is above four feet seven inches; the neck is covered with pointed feathers, and under the bill there is a tuft of stiff setaceous feathers, not unlike a brush. Its strength is so great, that it attacks sheep, lambs, and young stags, and even the chamois and ibex fall victims to its rapacity. It builds in such inaccessible precipices that its nest is very rarely seen. A smaller species of the same family, the *Vultur percnopterus*, although more properly an inhabitant of the south, extends its range to Geneva, where it is not uncommon.

2754. *The insects of Switzerland* are more numerous than the face of the country, so thinly clothed with wood, might lead us to suppose; and many peculiar species of trout and salmon abound in the lakes.

2755. *Of the domestic animals*, there is a good race of draught horses, some being not unfit for the carriage. They are generally compactly made, vigorous, and sober; while, to fit them for enduring the severe cold they are so frequently exposed to, nature clothes the head, limbs, and feet with an unusual quantity of long hair. The cattle are said to be of a large size, but the particular breed has not been mentioned.

2756. *The alpine Spaniel* (*fig. 358.*) is a remarkable variety of the Spanish breed, pre-

served with much care by the humane monastics on Mount St. Bernard. These beautiful dogs are generally two feet high, and full six feet long; the eyes have a peculiar appearance, attributed by some to the snow, and the high windy regions they inhabit. They are kept for the preservation of those unfortunate travellers who are so often lost in crossing the pathless snows of these dangerous mountains. Two of these dogs are sent out in severe weather, to scour the mountains, one with a warm cloak fastened to its back, the other with a basket

holding a cordial and provisions. Their instinct and sagacity is so great, that it is said they will discover persons perishing with cold and fatigue; and if too exhausted to proceed, they will lie close to these unfortunate travellers, to afford them warmth from their own bodies, and assist their resuscitation.

SECT. III. *Historical Geography.*

2757. *Ancient Helvetia* was celebrated among the Romans for the boldness of its natural features, and the rude valour of its people. The Helvetians were fully made known by the grand expedition undertaken with a view to make themselves masters of Gaul, and the discomfiture of which formed the first military exploit of Cæsar. They were soon after-

wards reduced to the state of a conquered people, when, like the rest of their neighbours, they found compensation for the loss of their valour and liberty by a culture and civilisation which had before been unknown to them.

2758. *During the middle ages*, Switzerland shared the fate of the rest of Europe, being over-run by the Huns, Burgundians, Franks, and other barbarous invaders. By them it was formed into a number of feudal possessions, under the supremacy, first of Charlemagne, then of the house of Burgundy, and lastly of the house of Hapsburg, which, having seated itself on the imperial throne, rendered Switzerland an appanage of the German empire. These invasions, and this degree of subjection, were, however, chiefly confined to the plain east of the Aar, on which are situated the cities of Berne and Friburg; while the regions of the Forest Cantons and the higher mountain valleys remained in a state of rude and pastoral independence, and their vassalage to the empire was little more than nominal.

2759. *The era of Swiss independence* had been prepared by the rise of the free cities, Berne, Friburg, and Glarus, which, surrounded by walls, began to defy the power of their liege lord. While the emperors, however, proceeded with discretion, their rights of feudal supremacy were not contested; but the violence of Albert, who endeavoured to make the whole of Switzerland an hereditary domain of his family, brought on a crisis. The most heroic resistance was made by the Forest Cantons, under the impulse received from the daring courage of Tell. A long struggle ensued; but the battle of Morgarten, in which the Austrian forces were completely routed by the mountaineers, secured the independence of Switzerland, though an hundred years elapsed before a full recognition of it could be extorted. A confederacy of thirteen cantons was formed; and the Swiss, engaged in wars among themselves, and with the neighbouring powers, soon acquired a high military reputation. Their infantry, an arm hitherto of little account, established its character as the first in Europe; and the battle of Morat, in which the duke of Burgundy was defeated and slain, spread the terror of their name throughout Europe. When they came into collision, however, with the great powers, and especially France, united and organising its force into regular armies, they could not maintain their ground; and in the battle with Francis I., at Marignano, their military strength was completely broken. Their reputation for valour, however, and the jealousy of powerful neighbours, secured them from any foreign invasion, till that great convulsion which shook the whole of Europe.

2760. *The French revolution* agitated all the monarchical states, to which it was in open and entire opposition; but Switzerland, which had so long presented to Europe a model of the purest forms of liberty, had seemingly nothing to fear. The Directory, however, soon showed that they employed the name of liberty chiefly with a view to the general subjection of Europe. They presented to the cantons a new form of constitution, which was called *unitaire*, and which the latter were required to adopt. As the Swiss clung to their old and venerated forms of freedom, an army was led into their territory, which, after a brave and even enthusiastic resistance on the part of the Forest Cantons, succeeded in compelling the whole to submit to French dictation. Switzerland became a new theatre of war between the French, Austrians, and Russians; but the first were finally triumphant. After the accession of Napoleon, the cantons made an attempt to regain their independence, which was repressed, though with some popular concessions; but the country was held as a vassal state; and Geneva and the Valais were incorporated with France. On the downfall of Napoleon's power, Switzerland again became an independent state, though the new division into twenty-two cantons has been retained, and the distinction of sovereign and subject states, certainly an odious feature of the old system, has not been resumed.

SECT. IV. *Political Geography.*

2761. *That free constitution*, which formed the boast of the cantons, was, in Berne, Friburg, and some others, modified by a large and somewhat severe mixture of aristocracy. Admission to public offices was limited to a few privileged families; and the sway over the Pays de Vaud, the Grisons, and other subject states, was somewhat rigorous. This distinction of sovereign and subject territories has now been happily obliterated, and even the interior predominance of aristocratic principles is much broken up; but each of the states has a particular constitution of its own, though all are united by the common tie of the federal government.

2762. *The Helvetic diet* consists of deputies from the different cantons, which meet once a year. Extraordinary meetings may also be called, on the requisition of any five cantons. This assembly takes cognisance of every thing that concerns the foreign relations and the general defence of the country. The diet has been much occupied by the unwelcome remonstrances made by the great sovereigns respecting the liberties taken by the press in regard to the conduct of foreign powers, and the refuge allowed to individuals who have become obnoxious through their support of liberal opinions. On these points, the diet, conscious of their own inferior power, have been generally obliged to yield.

2763. *The army of the Helvetic confederacy* is formed out of contingents which each canton, in proportion to its population, is obliged to furnish. From these are made out an entire amount of 33,000 men, which, if judiciously posted in the strong approaches to the country, might, it is supposed, secure them against almost any attack. But this, though seconded by the *levée en masse* of a brave peasantry, would not probably avail Switzerland in an unsupported contest with any of the great powers. In consequence, also, of the modern principles of war, which require the equal support of every point of an immense line of operations, it is supposed that a country holding this limitary position with regard to so many of the great powers cannot escape the occupation of its territory by one or other of them. A remarkable peculiarity in the military system of Switzerland is also the employment of its citizens in the service of foreign powers as a stipendiary force. This system has long prevailed, and is regularly authorised by the government. The number in 1816 was estimated at 30,000. The singular consequence follows, that these subjects of the most democratic state in Europe, form, in many cases, the main instrument in supporting the arbitrary power of foreign princes.

SECT. V. *Productive Industry.*

2764. *In the economy of Switzerland*, poverty must of necessity be a prominent feature. Many portions of its surface are absolutely inaccessible; a considerable portion of the remainder is incapable of yielding any thing that can conduce to the support of man; while even its most favoured spots are far inferior in productiveness to the fine plains of the neighbouring regions. Human industry, however, is employed with laudable zeal in extracting from an ungrateful soil the utmost possible amount of produce.

2765. *Agriculture* here is necessarily and strictly limited by nature. Wheat can be produced only in the finest plains of the low country; maize ceases to grow at the height of 2500 feet; potatoes, barley, and rye can only in favourable exposures be raised so high as 4000, though there are a few instances of their reaching above 5000 feet. The country is thus in a great measure dependent on its neighbours for the supply of grain; and its chief wealth consists in its pastures. The meadows are mown with peculiar care and diligence. In stormy nights, amid the rugged heights of the Alps, herdsmen watch in the chalets or rude log-houses, and call out continually to the cattle, otherwise they would take fright, and fall down the precipices. The produce of the dairy has been carried to great perfection in many districts, particularly those of Glarus, the Upper Engadine, and the plain of Friburg; and their Gruyère and other cheeses approach to the excellence of those of Lombardy. The Swiss cows give more milk than the Italian; nine cows producing daily a cheese of twenty-five pounds' weight. The people of Bergamo are celebrated for their management of sheep fed on the fine pastures of Mount Splügen. Generally, in these upper districts, the owner pastures his own little field; and a village in many cases holds one in common. But the increased population, and the consequent subdivision of property, has reduced them in many instances to severe distress. Wine, sometimes of considerable value, is made on the lower declivities of the hills, particularly in the Pays de Vaud, and there is an ample growth of timber, chiefly of fir and pine.

2766. *Manufactures in Switzerland* were long confined to rude products for domestic supply; but about the end of the last century, the cotton manufacture, in some even of its finer forms, was introduced into St. Gall and several of the southern cantons, and the looms, dispersed through the hills and upper valleys, enabled the peasantry to live in plenty, and caused an increase of population. In St. Gall alone, there are said to have been at one time from 30,000 to 40,000 females employed in embroidering muslin. Since the peace, however, the general and remarkable decline in the demand for manufactured goods has thrown many out of employment, reduced the wages of others, and produced great individual distress. Geneva has a long established and still extensive manufacture of watches. The number of workmen, indeed, which in 1782 was 5000, is now reckoned at 2027; but the value of watches exported is 3,000,000 francs, while in 1802 it was only 2,375,000. The improvement of skill and machinery seems to have increased the produce, while the number of workmen has diminished. There is also an extensive manufacture of this commodity in Locle, and other districts of the principality of Neuchâtel.

2767. *The commerce of Switzerland*, from its inland situation, is of course very limited, and consists chiefly in the exchange of its cattle for corn, colonial produce, and fine manufactures. Its central position occasions some inland transit trade between France, Germany, and Italy. The great road over the Simplon, though constructed by Napoleon for military purposes, produces very important commercial advantages. A wonderful combination of industry and boldness has been displayed in carrying roads across the most rugged and precipitous Alpine barriers. Such are the Devil's Bridge (*fig. 359.*), thrown over a fearful chasm, through which the Reuss thunders; the bridge over the Tesino; the road cut along the precipitous side of the Gemmi, about 1600 feet high. Across the great and rapid rivers

several large wooden bridges have been constructed ; but the largest, that at Schaff hausen,

359

DEVIL'S BRIDGE.

was destroyed by the French. The roads are generally good, especially in the canton of Berne, where they are carried to the tops of the highest mountains. Canals are scarcely known, or indeed compatible with the structure of the country. The one began near a century ago, to connect the lakes of Neuchâtel and Geneva, remains unfinished. The two cantons of Uri and Tesino completed in 1830 a very fine road over the St. Gothard, the passage of which was before only practicable for mules and horses. In traversing the Schellenen, it has opened a winding passage through enormous masses of granite, so as nowhere to

produce any laborious ascent. A new bridge is substituted for the famous Devil's Bridge, and the gallery of the Urnerloch is widened. The emperor of Austria has opened a superb route over the Splugen, with a view of facilitating the communication between Lombardy and the Tyrol, from which Switzerland derives great advantages.

SECT. VI. *Civil and Social State.*

2768. *The population of Switzerland* has not been ascertained by any very accurate census. The number upon which the contingent of the cantons has been calculated is 1,687,000; but this is now undoubtedly too small. The actual amount in 1827 was reckoned by Bernoulli at 1,978,000; but, by a careful estimate, in the learned Prussian work entitled *Hertha*, it is raised to 2,013,100.

2769. *As to national character*, the Swiss enjoy the reputation of being a plain, honest, brave, and simple people, among whom linger the last remnants of antique and primitive manners. Their fond attachment to their native country is conspicuous, even amid the necessity which compels them to abandon it, and to enter the service of the neighbouring powers. It is observed that no sooner is the *Ranz des Vaches*, a simple mountain air, played in their hearing, than the hardy soldiers melt into tears. An ardent love of liberty, ever since the grand epoch of their liberation, has distinguished the Swiss people. Now, indeed, the influx of strangers, and the general mixture of nations, is said to have broken down much of what was antique and peculiar in Swiss manners; and travellers have complained that every mode of turning to account their temporary passage is as well understood as in the most frequented routes of France and Italy. The manufacturing districts also have undergone a great change; but in the higher pastoral valleys there may still be traced much of the original Swiss simplicity.

2770. *The religion of Switzerland* is divided between the protestant and the catholic. Schweitz, Uri, Unterwalden, Lucerne, Zug, Friburg, Soleure, Valais, and Tesino are catholic: St. Gall, Appenzell, Aargau, and Grisons are mixed. The others may be ranked as protestant; though even in Geneva there are 15,000 catholics. The protestant churches were at first strictly Calvinistic, both as to doctrine and discipline; but the Genevan church has in a great measure renounced the tenets of this school of theology, and those who continue to profess them are even exposed to some degree of persecution. The presbyterian form of church government, however, still prevails throughout protestant Switzerland. The catholic religion exhibits this peculiar feature, that, instead of being, as usual, combined with high monarchical principles, it is established among the most purely democratic of the Swiss republics. The protestant cantons, however, are observed to be decidedly the most flourishing and industrious.

2771. *Learning*, though not very generally diffused throughout Switzerland, has been cultivated with great ardour at Geneva and Zurich, both of which have a character more decidedly intellectual than most European cities. The names of Haller, Lavater, Rousseau, Gessner, Zimmermann, and Sismondi throw lustre on Swiss literature. The great printing and bookselling trade which Geneva enjoyed while the French press laboured

under severe restrictions, has been diminished. Elementary knowledge is general throughout the protestant population; and the systems of education established by Pestalozzi at Yverdon, and Fellenberg at Hofwyl, have drawn general attention. The habits and general forms of life are substantially German, modified, in the western cantons, and especially in Geneva, by a somewhat intimate communication with France.

SECT. VII. *Local Geography.*

2772. *The following table exhibits the extent of the different cantons, and their population, according to an estimate formed in 1827:—*

	Square Leagues.	Contingent.	Popula- tion.		Square Leagues.	Contingent.	Popula- tion.
Geneva - - -	8	880	51,940	Zurich - - -	90	3700	221,370
Vaud - - -	140	2964	175,350	Friburg - - -	70	1240	83,700
Valais - - -	184	1280	71,300	Soleure - - -	26	904	52,030
Tesino - - -	106	1804	101,000	Basle - - -	24	918	54,380
Berne - - -	350	5824	357,710	Schaffhausen - -	16	466	32,140
Lucerne - - -	72	1734	118,500	Appenzell - - -	20	972	54,300
Uri - - -	48	236	14,240	St. Gall - - -	80	2630	148,250
Schweitz - - -	44	602	36,170	Grisons - - -	280	1600	87,900
Unterwalden - -	24	382	25,220	Aargau - - -	72	2410	151,510
Glarus - - -	42	482	27,660	Thurgau - - -	32	1520	80,730
Zug - - -	11	250	14,800	Neuchâtel - - -	30	960	51,880

2773. *Geneva (fig. 360.), though a small canton, is the most interesting of any, from the intellectual culture of its citizens, and the moral influence which they have exercised over Europe. It is situated at the western extremity of the lake bearing its name, where the Rhone, which has entered as a turbulent mountain torrent, issues a broad and pellucid stream. Geneva is not a handsome or well-*

built town: the lower streets are shabby, dirty, and ill paved; and the houses, four or five stories high, are overshadowed by awkward projections supported by wooden props. In the upper quarters there are some ranges of good houses; but the Genevans bestow their chief study on their country residences, which, commanding the most magnificent views of the lake and the Alps, are their constant abode, unless during the depth of winter. The government of Geneva is less democratic than formerly, the elections being no longer direct, but taking place by two stages: the aristocratic party also maintain their point of keeping up a small garrison, and shutting the gates of the city nightly, though the last is attended with considerable inconvenience. Geneva is a sort of literary capital, not only of Switzerland, but of this part of Europe. Both sciences and arts are cultivated with peculiar ardour. Even the ladies attend lectures, read, and draw, more than in any other city of Europe. The names of Calvin, De Luc, Saussure, Bonnet, Tissot, and other eminent men, adorn its literary annals.

2774. *The approaches to Mont Blanc, through the districts of Chablais and the Faucigny, belong politically to Savoy; but as they are usually made from the side of Geneva, the idea of Switzerland is invariably excited by this mountain and its mighty appendages. A journey of eighteen leagues leads the traveller to the Vale of Chamouni, one of the most re-*

361

markable spots in Europe, and where the fullest display is made of all the features of savage and Alpine grandeur. This valley was only discovered in 1741, by Pococke and Windham, but has since been visited by numerous admirers of the sublime in nature. It forms a long and narrow dell, through which the Aveyron (*fig. 361.*) dashes its impetuous waves, and above which rises, like a stupendous wall, Mont Blanc, with all its train of attendant mountains. Numberless glaciers, which have descended in successive ages, hang from its

sides in the most varied and irregular forms. The valley being only 3000 feet above the sea, Mont Blanc towers more than 12,000 feet perpendicularly above it, and with its attendants of Dôme du Gouté, Col de Géant, and La Côte, shoots numberless pinnacles or needles into the region of clouds, which alternately hide and disclose this awful range. By these gigantic objects Chamouni is as it were enclosed from the rest of the world. The first object of the traveller is to ascend Montanvert, where he enjoys a comprehensive view of these extraordinary scenes, and is on the borders of the "sea of ice," which spreads from this point for many leagues, with its surface broken like the waves of a stormy ocean. The bold traveller, exerting alike hands and feet, traverses these rugged masses, and in so doing, enjoys a variety of the most striking scenery. To behold, however, Mont Blanc in all its glory, it is necessary, by a rugged and even somewhat perilous route, to ascend the Breven; from which this loftiest of the European summits appears in full view, and its snows shine with a lustre which the eye can scarcely endure. The neighbouring summits of the Col de Balme and the Buet afford also fine views of Mont Blanc. For a few daring adventurers, a mightier task remains, that of scaling the sides of this king of mountains, and reaching its long unapproached pinnacle. It was not till about 1760 that Saussure, having his attention strongly directed towards Alpine phenomena, formed the daring conception of passing those walls of ice, those immense glaciers and unfathomable snows, by which it was guarded. He offered a reward to those who should trace before him this arduous path, or should even make an attempt, though abortive. Repeated efforts were made, but in vain, till 1786, when Dr. Paccard and James Balmat, having left Chamouni on the morning of the 7th of August, and spent the night on the mountain of La Côte, happily reached the summit at half past six on the following evening. At eight on the ensuing morning they reached Chamouni, with their faces and eyes swelled, and overwhelmed with fatigue. Saussure then determined, under the guidance of Balmat, to undertake the expedition in person. On the 1st of August, 1787, he formed a caravan of eighteen, furnished with provisions, poles, ropes, ladders, and scientific instruments (*fig. 362.*). They left Chamouni at seven in the morning, spent their first night on

362

ASCENT OF MONT BLANC.

the mountain of La Côte, and the second on the Dôme du Gouté, 11,970 feet above the level of the sea. Next day the declivity was found so steep, and the snow so hard, that they were obliged to cut steps in it with hatchets; but at eleven they had reached the summit, in the view of all the inhabitants of Chamouni, among whom Madame Saussure and her two sisters were observing them through a telescope; at which moment all the bells of the village were rung. The travellers near this highest point felt a quickening of the pulse, a burning thirst, extreme debility, and

difficulty of respiration. At every ten or twelve steps they were obliged to pause for breath, and spent two hours in going over the last 150 paces. These unpleasant symptoms have always been experienced by those who encountered the very rarefied air of the higher atmosphere. The next ascent was made by Colonel Beaufoy, and the most recent is that by Mr. Auldjo, who has published an interesting narrative of his route.

2775. *The canton of Vaud* formed originally part of the duchy of Savoy, from which, about the time of the Reformation, it was conquered by Berne; but that state, imbued with aristocratic ideas, communicated to its new acquisition few of the privileges which it had acquired for itself. It ruled the Pays de Vaud as a subject state, and with some degree of severity. In the shock occasioned by the French invasion, this territory obtained its emancipation, and exists now as a separate and independent canton. It occupies the whole northern border of the Lake of Geneva, which does not, like the southern, consist of Alps piled on Alps, but of gentle hills and smiling valleys, gradually sloping upward to the moderate elevation of the Jura. The vines of this region are considered equal to any in Europe; and the wine made from them has a very considerable reputation. Lausanne, the capital, enjoys perhaps the finest site of any city in the world. Placed in the very centre of the Lemman Lake, it commands a full view over that noble expanse, and those ranges of mightiest Alps, on the opposite shore, which are terminated by the awful and snow-clad pinnacles of Mont Blanc. These attractions, heightened by those derived from the adventures of Rousseau, and his celebrated romance, have drawn a multitude of visitors and residents from all parts of Europe, who seek there an agreeable and beautiful retirement. The

town, however, is neither large nor well built, though it has a fine Gothic cathedral. The house of Gibbon, and the cabinet where he wrote the last lines of his history, are visited by travellers. Vevay, farther up the lake, is a somewhat thriving little village, almost equal in beauty to Lausanne, and commanding singularly fine views towards the head of the lake. The house where Ludlow resided and died, the Castle of Chillon, and the Clarens of Rousseau, give to this place a classic character.

2776. *The canton of the Valais* extends from the head of the Lake of Geneva along the upper valley of the Rhone, which almost wholly composes it. The Valais is one of the most singular, picturesque, and romantic regions that are to be found on the globe. It consists of a deep valley, 100 miles long, and from two to twelve in breadth, shut in on both sides by the most enormous mountains that are to be found in Europe; on the south by the Italian chain, St. Bernard (*fig. 363.*), Monte Rosa, the Simplon, and St. Gothard; on the

363

CONVENT OF ST. BERNARD.

St. Maurice is so straitened, as to leave barely room for the river; and the gate of the Roman bridge there might shut in the whole Valais; but Napoleon formed a magnificent route by Meillerie, to lead to his great military line over the Simplon, which will favour indeed the commerce of the Valais, but will expose it to become the theatre of war. This territory is exposed above all others in Switzerland to the *goître*, that dreadful and disgusting malady, which at once deforms the body and destroys the faculties of the mind. The Valais is quite a rural district; yet its little capital, Sion, affords a market where its peasantry can exchange their cattle and the produce of their fields. This place, the *Sedunum* of the Romans, is picturesque and antique; its castle is perched on a pyramidal rock; and its old-fashioned walls, towers, and gates, suggest the idea of a fortified monastery. The baths of Leuk are situated 5000 feet up the declivity of the Gemmi. They are considered of great virtue in cutaneous disorders, and are therefore frequented, though little provision has been made for the comfort and accommodation of the visitors; nor do they find any of the usual amusements of watering-places; but they may enjoy the extraordinary grandeur of the views from the neighbouring summits, extending over the most elevated of the Alpine ranges.

2777. *The canton of Berne*, separated from the Valais by the great chain of the central horns or peaks, though shorn of its subject territories, holds still somewhat the most prominent place among the Swiss republics. Berne is divided into two parts, of which the northern, comprising a great part of the plain of Switzerland, is well cultivated by a laborious peasantry. The southern consists of the Oberland, or the declivity of the mountain range, a tract entirely employed in pasturage, where 300*l.* to 500*l.* is esteemed a fortune, and tiled dwellings and glass windows give to their owners a reputation of wealth. The pressure, however, of a redundant population has lately reduced them to severe distress.

2778. *The city of Berne* (*fig. 364.*), generally considered the capital of Switzerland, is

364

BERNE.

situated in the centre of the plain, in a commanding position above the Aar, which nearly encircles it on all sides. Fine and ancient woods reach almost to the gates of the city, bearing a noble and even majestic aspect. It suggests the idea of a Roman town; yet its handsomest houses and most sumptuous edifices date

all since 1760. The Gothic cathedral of the fifteenth century, the church of St. Esprit, the mint, and the hospital, are among its principal public buildings; while the private mansions are handsome, and solid rather than showy. But the magnificence of Berne is mainly derived from its wide and lofty terraces, commanding the most superb views over

the plain beneath, and the entire range of the Alps; from the spacious fountains by which its streets are supplied and refreshed, and from the fine avenues of trees which penetrate through the city. The constitution of Berne is the most aristocratic in Switzerland; and notwithstanding the diminished power of the state, this spirit is still in full operation. The scramble and contest for office, even among the nearest relations, is said in this small sphere to be as eager as in the greatest capitals. Berne is not, nor ever was, a literary town; yet it has a public library, to which some valuable collections are attached.

2779. *The region of the glaciers*, extending along the southern border of the canton, is, next to Mont Blanc, that where Alpine scenery is displayed on the grandest scale, and in the most awful and picturesque forms: the approach is by Thun, situated on the lake of the same name. This little city, more ancient than Berne, and still showing its strong castle seated on a rock, is interesting only by its vicinity to these sublime phenomena of nature, which the valleys of Lauterbrunn and Grindelwald (*fig. 365.*) afford the most favourable opportunity

GLACIER OF GRINDELWALD.

of viewing. These valleys contain rich pastures, and a considerable population; good roads, carried through every part of the canton of Berne, extend a considerable way up the mountains. They thus afford advantageous spots for viewing those vast scenes of ice, snow, and desolation, which are in their immediate vicinity. Here woods and meadows border close on immense glaciers, which, descending from the upper regions, cover an extent of about 1200 square miles of territory. From various points are descried those gigantic peaks which overlook this part of Switzerland, the Jungfrau or Virgin Peak, the two Eighers, the Wetterhorn, the Schreckhorn, the Finster-Aar-horn, and many others almost as lofty. Occasionally only, amid the clouds and mists which float continually around them, these mountains show the grandeur of their forms, and the pure white of the eternal snows with which they are covered. The scene is rendered more awful by the sound of the avalanche, which, in the higher Alps, is repeated at short intervals, like peals of thunder. Numerous and lofty cascades dash continually down these immense steeps; of which the most celebrated is the Staubbach (*fig. 366.*), formed by the Luschine, a tributary of the Aar: the stream

FALL OF STAUBBACH.

falls from the height of 800 feet, but as the mass of water is not very great, it spreads out in its descent into a species of white vapour, which, when illuminated by the rising sun, produces very brilliant effects. Other falls in the interior of the mountains are represented as equal or superior to the Staubbach. Two passages from this canton lead into the Valais; that over the Gemmi is one of the most remarkable of the Alpine passes. A great part of the road is cut in the face of a perpendicular rock 1600 feet high, and so smooth, that from below no vestige of a track can be discovered. Strangers, who are carried in a litter, must have their eyes bandaged, to prevent their growing giddy by looking down upon so fearful and dizzy a height. The passage of the Grimsel is not so perpendicular, but it is longer and more generally rugged, through a wondrous succession of peaks and glaciers. Near the summit is erected an *hospice*, where a man is stationed, with an allowance for receiving and entertaining travellers.

2780. *The Four Forest Cantons*, Schweitz, Uri, Unterwalden, and Lucerne, the cradle of Swiss liberty, form a territory situated to the east of Berne, and south of the Valais. Here Nature begins to lay aside that awful and rugged character which she wears in the southern chains, and in those enclosing the Rhone. The mountains are not so continuous, or so lofty; their upper regions are not covered with eternal snow, nor do fields of ice, descending from their sides, cover the surrounding plains. The two chief heights, those of Pilate and the Righi, rise solitary, like columns, to the height of 6000 or 7000 feet, above ranges which do not exceed half that elevation. This country is crossed in all directions by the Lake of Lucerne, or

of the Four Forest Cantons, of great extent, and shooting branches in every direction, which form each as it were a separate lake. Although the objects are not so grand as in the valleys of Chamouni or of the Rhone, yet the great variety of aspects, the interchange of rural and Alpine scenery, the numerous villages and farm-houses perched on the cliffs, render the banks of this lake, in the opinion of many, the most pleasing portion of Swiss landscape. Some of the mountains, from their solitary elevation, and the crumbling materials of which they are composed, inspire a constant apprehension of their breaking down; a dread which was realised about twelve years ago, by the fall of the Rossberg, which covered eight or ten leagues of territory with a chaos of ruins, and buried several villages, with 457 of the inhabitants, who were unable to effect their escape. All this territory is marked with spots memorable in the annals of history and patriotism; the scene of the exploits of Tell, and of the glorious resistance made by the little cantons to the overwhelming power of the house of Austria. Among the mountains, the most lofty and remarkable is Mount Pilate, about 7000 feet high, rising in seven peaks around a little lake, in which, according to the fanciful tradition of the country, Pontius Pilate drowned himself. It contains calcareous substances, with numerous shells and petrifications. The Righi, however, though little more than 5000 feet high, is the summit most frequently ascended by travellers. From its southern position, between the lakes of Lucerne and Zug, it forms a sort of outpost of the great body of the Alps, whence the entire middle chain of snowy peaks is seen from end to end, and behind them many summits of the Italian range, though those of Mont Blanc and Monte Rosa are hidden by the enormous masses in front of them. To the south appear the plains and lower vales of Switzerland, stretching away to the frontiers of France and Italy; and the view is so extensive, that from a cottage recently erected on this summit, the sun may be seen every day to rise and set over all Switzerland.

2781. *The cities in this pastoral region* do not attain to any important magnitude. Schweitz, the cradle of the Helvetic confederacy, to which it has given its name, is little more than a handsome village, situated amid the finest mountain pastoral scenery, rich meadows, and verdant knolls, embosomed amid rugged cliffs and Alpine peaks, tinkling with the sound of innumerable cow-bells, and echoing with the tune of the Ranz des Vaches. Lucerne, on the west, is considerably larger, and may be considered the capital of the Forest Cantons. It is nobly situated on an arm of the lake enclosed by Mount Pilate, and others of the loftiest heights in this part of Switzerland. The city itself is adorned by some ancient and venerable structures, and its different parts, separated by branches of the lake, are connected by wooden bridges of remarkable length and peculiar structure. The cabinets of Lucerne contain some interesting Swiss antiquities; but the object which especially attracts the attention of strangers, is the great model of the Four Cantons and the bordering tracts of Switzerland, which the late General Pfeffer spent a laborious life in framing. On a scale of fifteen inches to the square league, and of ten inches to the height of 9700 feet, he has modelled in relief all the objects of nature and art, every valley, every mountain and mountain path, every village, steeple, and even every cottage. The traveller here sees beneath his eye, in a narrow compass, all those mysteries of the Alps which it has cost him so much labour personally to trace.

2782. *The canton of Unterwalden* is likewise entirely mountainous and pastoral, enclosed by the high chain of the Suren Alps which surround it with an almost inaccessible rampart. They form a decided contrast to the soft pastoral valleys of the interior, particularly that which surrounds the little lake of Sarnen. Here all that is gloomy and rugged in Alpine scenery, its peaks of naked rock, its glaciers, its snowy mountains, and roaring torrents, disappear, and are succeeded by rounded hills of the most graceful form, covered with woods and the freshest verdure, and interspersed with rural abodes, which soften without impairing that character of stillness and solitude which reigns through every part of this romantic valley. Sarnen is the capital of what is called the Obwald; but Stantz, in the Nedwald, is the chief city of the canton. Uri, which only touches the lake at the south-east point by its little capital of Altorf, composes the fourth democratic canton. It extends to the south over a wild and awful range of the loftiest Alps, including that mass named Mont St. Gothard, which was supposed, till within this half century, to contain the most elevated peaks in Europe.

2783. *Zug is a little lake*, with an encircling canton, the smallest and least populous in Switzerland. The lake, whose waters are the deepest of any except Constance, is surrounded by pleasing pastoral hills, of but moderate elevation; on the south, however, the colossal heights of Righi and Pilate are reflected in its waters, and the dim forms of the glaciers appear in the distance. The town is seated on a hill so immediately above the lake, that in 1435, a whole street fell in, with its walls and towers, and sixty persons perished. The place is ancient, and has produced many warriors, who distinguished themselves both in the native and foreign service.

2784. *Zurich*, to the south-east of Zug, and approaching to the German border, is one of the most interesting of all the cantons, by its intelligence, industry, and prosperity. The long lake on which it is situated partakes not of the grand and awful character which

marks the scenery of the High Alps. Its hills, green to the summit, are covered with villages, culture, and habitations; nature appears only under a soft and pleasing aspect; though still, to the south, a dim view is obtained of the snowy ranges of the High Alps. The city of Zurich is situated on the Limmat, where it issues out of the northern extremity of the lake. Zurich is the literary capital of German Switzerland. Even in the middle ages it was called "the learned;" and the exertions of Zuinglius at that era to restore the lost rights of religion, reason, and humanity, threw a lustre on its name. In modern times its fame has been chiefly poetical and imaginative; and the works of Bodmer, Gessner, Zimmermann, and Lavater have excited interest throughout Europe. Painting and music have also been cultivated with greater ardour and success than in any other part of Switzerland. Zurich possesses a library of 40,000 volumes, with some manuscripts of importance: it has also valuable collections in the different branches of natural history.

2785. *The three cantons of Glarus, St. Gall, and Appenzell*, which extend along the eastern frontier towards Germany, present a somewhat different aspect from those of the west and centre. They are covered to a great extent with mountain ranges, which, rising to the height of 7000 or 8000 feet, do not reach the regions of perpetual snow, or pour down avalanches or glaciers into the plains beneath; but rise in varied shapes, dark, rugged, and awful. One of the leading features is the Lake of Wallenstadt, twelve miles long and three broad, where the naked cliffs rise in picturesque grandeur to an amazing height, and dip so perpendicularly into the water, as to leave very few points at which a boat can approach. These mountain walls elsewhere enclose luxuriant valleys, which open as they proceed north toward the Lake of Constance; and a great part of St. Gall and Appenzell presents a level surface. Into these cantons the cotton manufacture has been introduced on a great scale, and has converted the hardy huntsmen and husbandmen of the Alps into weavers and embroiderers. For some time a great increase of wealth was thus produced. On the return of peace, however, the stagnation of demand, and the formidable rivalry of Britain, threw a great number out of employment. When M. Simond passed through in 1817, he witnessed extreme distress; beggars swarmed every where, and many were suspected to have died of famine, or at least of deficient nourishment. A considerable revival, however, is said to have recently taken place. At the same time, the original simplicity and honesty of the Swiss is supposed to have been greatly impaired by this change of habit.

2786. *Among the small capitals of those three cantons*, St. Gall is the most important and the most ancient. During the ninth and tenth centuries, it was considered as the greatest seat of learning in Europe. This ray of light emanated, it is said, from Icolmkill in Scotland, of which the patron saint of this place was a native. Many of the manuscripts used in the early editions of the classics were drawn from the archives of its monastery. Its abbots were princes of the German empire, through whom and its nobles the city was involved in war and politics; and, being eclipsed by more modern schools, lost its fame for learning. The monastery was suppressed in 1798; and the canton is divided between Catholics and Protestants, the former being 99,000, and the latter 58,000. Appenzell has adopted the manufacturing system in its fullest extent; and on its limited territory maintains the most dense population of any part of Switzerland. Though removed beyond the domain of the Higher Alps, it has several steep summits, which command extensive views over the neighbouring territories of Tyrol and Swabia. The population of Appenzell is divided into two quite distinct portions: the rural, which is almost all catholic; the manufacturing and commercial, almost wholly protestant. Glarus is situated among the most rugged and rocky tracts of this part of Switzerland. The town lies deep in a valley, overhung by ramparts of rock so elevated, that the sun in winter is seen only for four hours of the day. This buried situation, narrow crooked streets, its diminutive and antiquated houses, with low entrances, heavy doors, and walls painted in fresco, the silence and stillness which prevails, unite in suggesting the idea of a city dug out of the earth, like Pompeii or Herculaneum. Near the place is a mass of rocky fragments, which fell in 1593 from the top of the Glarnisk, a height of about 8000 feet.

2787. *Thurgovia, or Thurgau*, which stands on the Lake of Constance, and on the Swabian border, is a tract in which Switzerland loses almost entirely its peculiar character. Only to the south, on the side of the Tockenbourg, rise hills of 2000 or 3000 feet high, covered with rich meadows and Alpine pastures. The rest consists of valleys and plains of extreme fertility, covered with vines and rich harvests. Two crops of flax are raised in the year, and an extent of several leagues is covered with plantations of pears and apples, from which excellent cider is made. There are manufactures of very fine linen, which are still carried on, though the trade is injured by the general use of cotton stuffs. This territory, previous to the late revolution, was in a very oppressed state. Eight of the other cantons had possessions within it, which they ruled by bailiffs with great severity; and numerous lords and convents had seigniorial rights, rendering those liable to them little better than slaves. It is now erected into a separate and independent canton, of which the little city of Frankenfeld, the ancient residence of the bailiffs, is the capital.

2788. *The city of Constance*, though now belonging to the Grand Duchy of Baden, is

locally attached to Thurgau and to Switzerland. Constance, during the middle ages, was one of the great imperial cities, possessing a population of 36,000 souls, extensive linen manufactures, and a great inland trade. In the fourteenth century it became more celebrated by the great council, which attracted 2300 princes and nobles, 18,000 ecclesiastics, 80,000 laymen, and, it is added, 1500 courtesans. The Romish church was then in its utmost height of power; the archduke of Austria was put to the ban of the empire; John Huss and Jerome of Prague, the early movers of the Reformation, after having appeared under a safe-conduct from the emperor, were ignominiously kicked out of the council, and hurried to the stake. This spiritual tumult seems to have banished from Constance the industry by which it had flourished; and when, in 1548, it fell under the yoke of Austria, its decline became still more rapid, and its population is now reduced to 2000 souls: the grass grows in the streets, the iron doors turn on plated hinges, and have the figures of warriors carved on them; and the great hall, 153 feet long and 60 broad, in which the council met, is now employed as a yarn market. Constance is, however, beautifully situated on the lake of that name, called by the Germans the Bodensee. This wide expanse appears divested of all the awful grandeur which marks the interior regions; but the wide circuit of its cultivated shores, swelling into gentle hills, bears an aspect peculiarly soft and pleasing. Although this lake be every where surrounded with level country, it has the deepest water of any in Switzerland.

2789. *Schaffhausen* is a small canton, which, situated entirely on the north or German side of the Rhine, scarcely belongs to Switzerland, unless through political ties arising out of peculiar circumstances. The capital was originally an imperial town; its burghers extended their possessions till, with a view to security, they sought and found admittance into the Helvetic League. The territory of Schaffhausen is diversified by hills of moderate elevation, thickly planted with vines, the produce of which is held in estimation. The town of Schaffhausen was distinguished by a magnificent wooden bridge over the Rhine, constructed in 1758 by an artist of the canton of Appenzell; but this celebrated erection was burned down by the French in April, 1799, when the Austrians obtained possession of Schaffhausen. It is still, however, distinguished and visited on account of one of the grandest phenomena of nature, the great fall of the Rhine (*fig. 367.*); to which Europe presents

FALL OF THE RHINE.

nothing equal, and which disputes, in some points, the pre-eminence with that of Niagara. Neither its height, indeed, which does not exceed sixty feet, nor the mass of its waters, can enter into comparison with its rival; but in the violence of its fall, the sound of its thundering waves, and the cloud of foam which it throws into the air, it is almost matchless. The human voice is not heard in its close vicinity, and the sound reaches to the distance of six miles.

2790. *Basle* forms another frontier canton, and has also characters which make it only imperfectly Swiss. A steep mountain chain shuts it completely in from the rest of Switzerland, no part of which can be reached without crossing it. The slopes of this chain, in looking towards Basle, and descending to the fertile plain on the Rhine, are covered with rich pastures. Basle was founded by the Romans, and remained always a city of consequence during the middle ages; but it was in the fifteenth century that it rose to its greatest splendour. Advantageously situated on the Rhine, which here begins to be navigable, and placed at the point of union between France, Switzerland, and Germany, it attained a high degree of commerce and wealth, and distinguished itself likewise by a zealous cultivation of literature and the arts. That of painting was early carried to perfection; and the names of Erasmus (as a resident), Paracelsus, *Æcolampadius*, to which it has since added those of Euler and the Bernoullis, gave it a distinguished name in the world of letters. Basle, though it has lost much of its former importance, is still the seat of a great transit trade; and forms an important military position, from its command of the first stone bridge over the Rhine. In the fine arts, this city could boast of Holbein, an eminent painter, many of whose best works still adorn its edifices.

2791. The three cantons of *Argovia*, *Soleure*, and *Friburg* stretch from Basle in a south-westerly direction along the course of the Aar. They compose, along with part of Berne, the great plain of Switzerland, enclosed on one side by the ridge of the Jura, and on the other

by the great range of the central glaciers. This plain presents not the same dead level as those of France and Italy, but is diversified by detached hills and branches of the Jura, some of which rise even to the height of 5000 or 6000 feet; but these hills are green to the summit, generate no glaciers, and in summer throw off altogether their covering of snow. This district, accordingly, contains the richest pastures in Switzerland, whence are produced the Gruyère and other cheeses, which enjoy so high a reputation throughout Europe.

2792. *The cities of this district* are among the most important in the confederacy. *Friburg*, picturesquely situated, partly on an irregular ridge of rocks, surrounded with walls and towers, partly on the plain beneath, forms a sort of capital of catholic Switzerland. The aristocratic spirit was carried in Friburg to an extraordinary height; the magistrates had even, as at Venice, a secret council, by whose invisible machinery all affairs of state were conducted. An eminently exclusive spirit still prevails, which shuts the door against new men and new ideas, and opposes those modern improvements which have found a place in the neighbouring cantons. Some steps, however, though on a contracted scale, have been taken towards the instruction of the lower orders. *Morat*, in this canton, a small town on a little lake of the same name, is immortalised by the splendid victory gained by the Swiss in 1498 over the great army of the Duke of Burgundy, commanded by Charles the Rash; a victory which, after their long struggle, sealed the existence and independence of the Helvetic confederacy. On the spot was erected a chapel (*fig. 368.*) to which the

368

CHAPEL OF WILLIAM TELL.

votaries of freedom came in pilgrimage, and where the Swiss held a regular anniversary of this great day; but the French, trampling upon every solemn and exalted feeling, burned it to the ground, and erected in its stead their own tree of liberty. *Soleure* is a small town and canton, governed by the same aristocratic spirit as Friburg. The canton includes some part of the range of the Jura; and the *Weissenstein*, a summit immediately behind the city, commands, according to *Ebel*, the finest

view of the whole range of Swiss mountains that can any where be obtained. *Aarau* is a small town in the plain of Argovia, celebrated for its rich meadows, and the skill with which they are irrigated. *Aarburg*, in the same canton, deserves notice, as the only fortified town in Switzerland.

2793. *The canton of Neuchâtel*, including *Vallengin*, covers a long line of the summits and valleys of the Jura. This extensive ridge, which, in a direction from north-east to south-west, separates Switzerland from France, does not reach that immense height, nor exhibit those rugged and broken forms, which give to the southern chains so grand an aspect. It rises in the form of a steep high terrace, resembling, from a distance, a lofty wall. The summit commands the most extensive and delightful views over the plain of Switzerland, and the vast ranges of Alps beyond. The sides being neither covered with perpetual snow, nor subject to the inroad of glaciers, are clothed with large and dense forests of fir in the upper regions, and below chiefly of walnut trees; groves of which enclose almost every village. The political constitution of Neuchâtel presents several anomalies: it has long been subject to the King of Prussia, a sovereign absolute elsewhere, but here strictly limited, exercising the executive power by his governor, but leaving the legislative functions in the hands of the people. Neuchâtel has another relation, by which it forms one of the confederated cantons of Switzerland. On the whole, the people of this district have long enjoyed civil and political rights more ample than in most other parts even of Switzerland; and they accordingly drew numerous emigrants from the aristocratic cantons. Thus encouraged, and stimulated by the difficulties with which they had to contend, they have displayed an industry and ingenuity worthy of admiration. Not only the ground is carefully cultivated, but manufactures, especially watchmaking, have been carried to great perfection.

2794. *The interior details of the Jura* possess considerable interest. The long lake of Neuchâtel, twenty-seven by six miles, extends along its base, overhung by the rocks and woods of the mountain ranges above. A good deal of timber, floated down from the heights is conveyed along this lake and the smaller one of *Bienne*, which is prolonged in the same direction to the *Aar* and the *Rhine*. Neuchâtel is a small, well-built town, finely situated above the lake near its northern extremity, and commanding delightful views over a great part of Switzerland. A Mr. *David Pury*, one of its citizens, who made a fortune of 6,000,000 livres, left the whole to be employed in the improvement of his native city. There are still remains of the now ancient castle from which it derives its name. *Yverdon*, at the opposite end of the lake, is also an ancient and agreeable town. The inhabitants are distinguished by intellectual culture, and their city by the residence of *Pestalozzi*, and by the

schools formed according to his ingenious system. The high valleys of Locle and Chaux de Fond consist almost entirely of rocks scattered with the wildest and rudest irregularity ; yet they are covered with a thriving and industrious population, employed in the making of lace and watches. The natives of these valleys have distinguished themselves by many important inventions in the latter art. A remarkable object near Locle consists in a deep hollow sunk into the heart of a mountain, near the dark bottom of which are three mills, placed vertically one above the other. In the valley of Travers is Motiers, celebrated by the temporary residence of Rousseau, who has also given distinction to the little lake of Bienne and its island of St. Pierre ; though it does not, in M. Simond's opinion, display any picturesque beauty corresponding to the enthusiasm with which he describes it.

2795. *The Grisons* form an extensive canton in the south-east, bordering on Italy and the Tyrol. They ranked, till lately, rather as allies than members of the Swiss confederation, being formed into a league, or rather two leagues, called the Grey League, and the League of the House of God, to which was even added another, called the League of the Ten Jurisdictions. They are now incorporated with the rest of Switzerland under the character of a canton, and form a very extensive one. The district is altogether mountainous and pastoral, though nowhere rising to that extraordinary elevation which is attained by the more westerly chains. Mount Splugen, however, almost rivals the rugged horrors of the valley of Schellenen : the Rhine in its early course flows along its northern border. A road, passable in summer for carriages, has lately been, with great labour, constructed over the Splugen, and forms one of the principal passages into Italy. The people are rather a peculiar race, composed in a great measure of the descendants of the ancient Rætians, who speak singular dialects, called Roman and Ladin ; being compounded of the Latin with that of the original native tribes. The Grisons have an interior government entirely popular, divided into twenty-six jurisdictions, each of which is a little republic in itself : the towns are small, situated along the course of the Rhine. Coire or Chur, the capital of the canton, and the original seat of the League of God's House, is an ancient episcopal city, still containing some Roman monuments, and a cathedral of the eighth century. Dissentis and Truns, at which latter the Grey League was signed, are only agreeable and picturesque villages.

2796. *The new canton of Tesino*, extending along the Italian border, includes the southern slope of that loftiest range of the Alps by which Italy is separated from Switzerland. It is composed of a succession of about thirty Alpine valleys, among which the chief are Leventin, Riviera, Brenna, and Bellinzzone, which, though of great elevation, enjoy, in consequence of their fine southern exposure, a much milder climate, and produce grain on sites more elevated, than can be done on the northern side of the mountains. Their pastures, indeed, are less rich, not being fed by those numerous streams, which descend from the snows and glaciers of the higher Alps. The whole country, however, and particularly the shores of the great lakes of Maggiore and Lugano, with their ornamented islands, present almost an Elysian aspect. Yet this, the most favoured by nature of all the cantons, is debased by a poverty, an indolence, and a neglect of culture unknown in any other part of Switzerland. The meanest races in German Switzerland are superior to those of this district ; it has even been said that not a hog exists there which would content itself with the habitations in which the peasantry reside. The people are in fact of Italian origin, and never enjoyed that independence which is the genuine birthright of the Swiss peasant. Their different valleys were respectively subject to Unterwald and the other cantons, who, as too often happens with democratic states, proved the most oppressive of all masters. Under the last arrangement, however, this yoke was broken ; and Tesino, being now formed into an independent canton, may gradually emerge from its present depression.

2797. *The local features of this canton* are varied and singularly beautiful. The three lakes of Maggiore, Como, and Lugano, though partly belonging to Italy, are in a great measure included within it, and they combine Alpine sublimity with all that is soft and rich in Italian landscape. The Lago Maggiore, which extends forty-four miles in a winding line from north to south, with a breadth nowhere exceeding seven miles, presents many enchanting spots, among which the Borromean Islands are particularly admired. Originally masses of naked rock, they were, by the care of Prince Borromeo of Milan, formed into terraces, and covered with the most brilliant vegetation : they command magnificent views, on one side upon the chain of the Alps, and on the other upon the plains of Italy. Locarno, a small town, finely situated at the northern head of the lake, serves as a market to the inhabitants of the numerous Alpine valleys which open into it. Lugano, on the lake of the same name, is the largest town in the canton, and has a considerable number of churches and convents. The Lake of Lugano is broken into several gulfs, all of which display the most picturesque and enchanting scenes. It abounds remarkably in fish, of which 20,000 to 30,000 quintals are sent weekly to Milan. This territory has given birth to many eminent architects. The northern head of the Lake of Como is enclosed by some of the rudest mountains of the Grisons, where the scene passes gradually into the rich and ornamented plain of Lombardy. Meantime the dignity of capital of the canton is given to Bellinzzone ; a pleasant small town, commanding the Val d'Airolo, and consequently the passage over the St. Gothard. By this road there

is a constant conveyance of cattle and horses, of which an extensive autumnal market is held near Bellinzona. A remarkable battle was fought here in 1422, between the Swiss and the Duke of Milan.

CHAP. X.

GERMANY.

2798. *Germany* is an extensive country, situated in the centre of Europe, and exercising a most powerful influence in the political affairs of that continent. There is a peculiar complication in its geography; for not only is it divided into numerous states, of every varied dimension and description, but several of these have large portions of the neighbouring countries, particularly of Poland and Italy, incorporated into their territory. We propose, however, in our description, to preserve that of Germany as much as possible distinct and entire, only exhibiting, under the political section, the general jurisdiction and resources of the great states, from whatever source these may be derived.

SECT. I. *General Outline and Aspect.*

2799. *Germany proper* is bounded on the north by the German Ocean or North Sea, by Denmark and the Baltic; on the east by Poland and Hungary; on the south by Italy and Switzerland, from which it is separated by the vast chain of the Alps; on the west by France, Belgium, and Holland. It lies nearly between 45° and 55° north latitude, 6° and 19° east longitude; extending about 700 miles from north to south, and 550 from east to west. Its entire dimension is estimated by Hassel at 11,664 German square miles, equal to about 256,000 British.

2800. *In its surface*, Germany, in different parts, presents remarkable contrasts. The southern border is formed by the Alps, the loftiest and steepest chain in Europe. The Oertles and the Great Glockner, in the Rhætian or Tyrolean Alps, are respectively 14,400 and 12,000 feet high; scarcely inferior to the highest in Switzerland. From this main southern barrier, lower branches descend and cover a great part of the interior country; the Black Forest in Swabia; the Seven Mountains on the Rhine; the metalliferous chain of the Hartz in Bohemia and Saxony; and the forest of Thuringia. Of these, however, few rise higher than from 3000 to 4000 feet. They terminate about the middle of Germany, and the whole north forms a portion of that vast continuous plain which reaches from the Bay of Biscay to the frontier of Asia. On the extreme north it falls so low that dikes and other barriers are necessary to prevent it from being overwhelmed by the ocean. This very level surface, and the great extent of sand impregnated with marine exuviae, suggest the idea that this region had emerged from the sea more recently than the southern division. Notwithstanding the disadvantages occasioned by rugged mountains in the south, and sandy plains in the west, Germany is on the whole a very productive region. Its finest soils are found in the intermediate tracts, between the steep elevations of the south and the dead flats of the north. The latter are best fitted for corn; while vines and fruits cover the declivities and valleys of the southern territory.

2801. *The greatest rivers of Europe* roll through Germany in various directions. The sovereign Danube rises in its furthest eastern border, from the heart of the Black Forest, in the duchy of Baden. Formed by the union of three small streams, it flows nearly due east through the whole breadth of southern Germany, watering the dominions of Wirtemberg, Bavaria, and Austria; and then continuing through Hungary and Turkey, till it terminates in the Black Sea. Its course through Germany is estimated at 432 miles. It becomes navigable at Ulm; but the current being afterwards obstructed by cataracts, it contributes less to internal commerce than any of the great German rivers. From the grand Alpine boundary on the south it receives important streams, the Lech, the Iser, the Inn, the Enns; but on the opposite side the Bohemian mountains press it too closely, and direct all their waters northwards. The great Illyrian tributaries, the Save and the Drave, though partly German, do not enter the Danube till after passing the Hungarian frontier. The Rhine rises in the heart of Switzerland, from the rocky pinnacles of St. Gothard; and in approaching Germany passes through the Lake of Constance, where for some further space it divides Germany from Switzerland, and afterwards from France. Near Landau it enters Germany, within whose borders it pursues its course, till, passing into the Netherlands, it spreads into several broad estuaries, and reaches the ocean. Its largest eastern or German tributary is the Mayn, which flows through Franconia, and by its junction marks the commencement of the Lower Rhine. From the same side come the smaller streams of the Neckar, the Lahn, the Ruhr, and the Lippe. The Moselle and the Meuse, which pour in large accessions from the west, belong more to France than to Germany. The Rhine is

navigable from the point where it leaves Switzerland, and is of signal benefit to internal commerce. The other great rivers are altogether German. The Elbe rises on the frontiers of Silesia, and follows a winding course through Bohemia, where, by its tributaries the Moldau and the Eger, it drains all the waters of that mountainous region. Thence it enters Saxony; and after pouring a broad stream through the various territories of northern Germany, flows, by a wide estuary, into the German Ocean. Its entire course is reckoned by Hassel at 523 miles. It receives fifty-three tributaries; of which the principal, besides those already mentioned, are the Saale, bringing the waters of the Unstrut, and the Havel bringing those of the Spree. The Elbe is a navigable river of vast benefit to German commerce. The Oder, a Prussian river, rises in Moravia, flows through Silesia, Brandenburg, and Pomerania, and enters the Baltic by three mouths, after a course of 392 miles. It receives the Neisse and the Bober. The Weser, the river of Westphalia, is formed by the union of the Werra and the Fulda. From that point, under the name of Weser, it has a course of 200 miles; the previous course of the Werra had been 126 miles. The navigation is good both on the Weser and its tributaries.

2802. *Few lakes* of any consequence are formed by the German waters. The Lake of Constance, indeed, called by the Germans the Bodensee, has the greater part of its circuit in Germany; but it may be more properly classed with the lakes of Switzerland. The Lake of Garda, though it touches the Tyrol, is more than half Italian. All the others are small and local features. On the coast of the Baltic there are some *haffs*, which are, strictly speaking, bays, being connected with the sea by narrow channels.

SECT. II. *Natural Geography.*

SUBSECT. 1. *Geology.*

2803. I. *Primitive and transition districts.* The primitive and transition districts in Germany are the following: — 1. The more central parts of the Alps, from the east of Switzerland to the plains of Hungary. 2. The western, or the ranges on the west side of the Rhine, which includes much of the Black Forest (Schwarzwald), the Odenwald, and the Spessart. 3. Rhenish slate mountains, in north-western Germany, which extend from W. N. W. to E. N. E. 4. Hartz mountains, in the kingdom of Hanover. 5. The great eastern primitive and transition country, including the mountainous parts of Bohemia, Moravia, Silesia, Saxony, and part of Bavaria; bounded on the *south* by the Danube; on the *west* by the flat country of Regensburg, Amberg, Bayreuth, Coburg, Meiningen, Berka; on the *north* by the plains of Thuringia, Saxony, Lower Lusatia, and Silesia, in the neighbourhood of Eisenach, Rudolstadt, Altenburg, Leipzig, Wurzen, Grossenheim, Görlitz, Lauban, Lignitz, and Breslau; on the *east* by the flat country on the Oder and on the Lausitz; and forming a great connected system.

2804. *Primitive rocks.* The chief Neptunian rocks of this division are gneiss and mica slate, with subordinate clay slate, whetstone, limestone, and hornblende rock: the Plutonian are granite, syenite, &c.

1. *Gneiss.* Sometimes the felspar in the gneiss is in the slate of *kao-lin* or porcelain earth, as at Hafnerzell, on the Danube. Occasionally it contains talc, or crystals of hornblende; more rarely the mica is supplanted by *graphite* or black lead, or the graphite is disposed in veins, as at Hafnerzell, Ruderding, Langensdorf, Leitzerberg, and Zwiesel, in Bavaria; and in different parts in Lower Austria. In the western Böhmerwald, the mica in the gneiss is replaced by *iron mica*, small contemporaneous veins of the Neptunian granite of the Schwarzwald, and other ranges. 2. *Mica slate.* This rock exhibits its usual characters; is observed passing into gneiss, and also alternating in beds with that rock.

2805. *Subordinate primitive rocks.* Clay slate, limestone, and hornblende rock, are the principal subordinate primitive rocks.

1. *Clay slate.* This rock, which is almost entirely composed of minute scales of mica, rests upon the mica slate, and also alternates with it. These three rocks occur more or less distinctly stratified; and in many parts in Germany the direction of the strata is from N. E. to S. W.

2. *Limestone.* This rock, which is in the state of marble, occurs not in regular, continuous, and extensive beds, but also in comparatively short beds, many of which are sometimes observed in the same mountain following each other in interrupted succession for miles.

3. *Hornblende rocks.* Fine displays of these rocks occur in the gneiss of the Böhmerwald; and enclose, as is the case in Scandinavia, repositories of *magnetic iron ore*. There is a remarkable resemblance in the primitive Neptunian rocks of both countries. In the Böhmerwald we find not only the same varieties of gneiss, but also the same subordinate beds, as occur in Scandinavia; also similar veins and masses of granite, containing many different minerals of the same species as those which were formerly considered as characteristic of the northern primitive region. Thus we find in the western part of the Böhmerwald, in the true primitive centre of Germany, the *albite*, *triphane*, *petalite*, *tantallite*; and in the eastern half of that chain, on the Moravian frontier, the red and green *Norwegian garnet*, the *epidote* of Arendal, and the same black *augite* and *coccolite* as in Scandinavia.

Further, the *malacolite* of Pargas occurs in the limestone of Zitesch, and there also the well-known combination of *garnet* and *idocrase*. Lastly, the hornblende rocks of Weisseburg contain *epidote* and *prehnite*, those of Jamoliz *harmotome*, and of Marchendorf *stilbite*. The *lepidolite* of Rozena in Moravia occurs in a mass of granite enclosed in gneiss; and it is said the same locality affords also *tin ore* and white *topaz*.

4. *Whitestone*. This rock sometimes encloses masses of gneiss, and is frequently surrounded with gneiss, mica slate, and clay slate. It often contains embedded crystals of *garnet* and *cyanite*; less frequently of hornblende, mica, quartz, and copper pyrites. It generally rests upon gneiss, and is observed passing into that rock, and also into a kind of Neptunian granite. It is a more abundant rock in Germany than in any other country. Saxony; the southern Böhmerwald-Gebirge, on the Austrian and Moravian frontier; the Alps of Salzburg, of Styria, and Lower Austria, contain deposits of this rock.

5. *Serpentine*. Some varieties of this rock occur embedded in limestone in Neptunian strata, and therefore these are probably of aquatic origin.

2806. II. *Transition rocks*. *Neptunian*. These are clay slate, with quartzo-talcy or micaceous rocks, and older greywacke; newer greywacke, with newer clay slate; transition

limestone, flinty slate or Lydian stone, whet slate, anthracite. 1. The older greywacke and the talcy rocks connect the transition and primitive deposits with the newer greywacke and clay slate, the transition and secondary rocks. 2. The newer or *true* greywacke and its clay slate sometimes contain organic remains, as in the Hartz, Bohemia, Rhine district, &c. The fossils from the animal kingdom are generally *casts*, or they are changed into limestone or brown ironstone. The most frequent are *trilobites*, or fragments of *encrinites* and *madreporites*: fossil bivalve shells also occur, such as *terebratulites*, *ammonites*, *orthoceratites*, &c. Some plants are likewise met with, and are generally *calamites*.

2807. *The limestone occurs in interrupted beds, thus exhibiting the same mode of distribution as in the primitive deposits.*

2808. (3.) *Limestone of the talcy quartz rocks.* This in general aspect approaches more nearly to the primitive limestone than any of the others of the transition class. Many of the beautiful *brecciated marbles* of commerce belong to this part of the geological arrangement. *Limestone of the true greywacke* is more compact than the former, and also differs from it in frequently containing fossil organic remains, viz., *trilobites*, *calymenites*, *asaphites*, *orthoceratites*, *madreporites*, &c. Many of these limestones, when cut, have a beautiful appearance, and are highly valued as *marbles*. *Caves*, containing remains of extinct animals, occur in the limestone.

4. *Flinty slate and Lydian stone.* These minerals occur in beds in the greywacke and clay slate. It is remarked that the greywacke and clay slates, in districts where the beds of flinty slate occur, are sometimes highly impregnated with silica, a fact intimately connected with the mode of formation of all these rocks.

5. *Whet slate or whetstone.* This slate, so well known in the arts, occurs in small beds in some districts in the clay slate.

6. *Anthracite, or glance coal.* Beds of this coal occur in the Hartz, Westphalia, and Bohemia.

2809. *Plutonian primitive and transition rocks.* — *Granite.* Those great bodies of granites, which are intermixed with the Neptunian primitive strata at their junction, and which also send out branches or arms among those strata, may be considered as of primitive formation; while the granites, which are confined to transition rocks, and affect them in the same manner as the primitive does the primitive strata, may be viewed as belonging to the transition class. The Alps, Reisingebirge, the Erzgebirge, the Böhmerwald-gebirge, the Harzgebirge, afford examples of these granites.

2810. *Syenite.* This rock in general is said, in Germany, to be newer than many even of the transition rocks. It may be well studied in Moravia, where it abounds. The trap rocks connected with the syenite belong to the same epoch of formation.

2811. III. *Secondary rocks.* *Neptunian.* The old red sandstone and mountain limestone, the oldest members of the secondary class, are comparatively less frequent and abundant in Germany than in Britain and Ireland. The coal formation occurs in Silesia, Westphalia, Saxony, Bohemia, Moravia, and in other quarters; but in insignificant deposits, when contrasted with its extraordinary abundance in Britain. The most extensive coalfields are those in Silesia. In many places, as Halle, Zwickau, Tharandt, Forest of Thuringia, and also in Silesia, the coal formation is more or less completely covered with that red sandstone known under the name *roth liegende*.

2812. *The secondary formations* that succeed the coal deposit may next be noticed.

2813. *Magnesian limestone, or zechstein.* This formation was at one time believed to form a principal part of the great limestone range of the Alps; hence was named Alpine limestone: the truth, however, is, that it occurs in but small quantity in the Alps, the limestone of that range belonging to a newer formation. It is of comparatively small extent, and its colours are grey, brown, yellow, and black. The fossil organic remains which most particularly characterise it are *fishes* of various kinds, and particular kinds of *amphibia*. Fossil crabs of the *trilobite* tribe, and the *productus longispinus* of Sowerby, occur in it. *Terebratulites* and *encrinites*, particularly the *E. ramosus* and *T. alatus, cristatus, lacunosus*, and *sufflatus*. Impressions of flustra also occur, and fossil mytili and tellinæ. Fossil fruits, and impressions of sea and land plants, add to the variety of organic remains in the formation. It occurs in the Hartz, Hessia, Hanau, Thuringerwald, Schmalkalden, Frankenberg, &c.

2814. *New red sandstone.* This vast deposit is divided in Germany into three great systems: an inferior and superior red sandstone, each abounding in variegated marls, the one separated from the other by a great limestone formation called the *shell limestone*, or *muschel kalk*. The lowest system of *variegated limestone* contains a good many interesting fossil plants, chiefly *coniferæ* and *ferns*; also bivalve and univalve shells, approaching very nearly in character to those of the *shell limestone* and upper formations, but, as well as the plants, differing essentially from any fossils of the magnesian limestone and lower formations. It frequently contains *salt* and *gypsum*.

2815. *Shell limestone.* This formation is seen in Wirtemberg, Bavaria, Gotha, and Hanover, resting upon the variegated sandstone, and capped by *keuper*. All the *salt-mines* in the kingdom of Wirtemberg occur in it. Jäger found in it fossil remains of several remarkable extinct amphibious animals: these are *plesiosaurus*, *ichthyosaurus*, and an unknown *reptile*; and the jaws and teeth of a *crocodile*, plates of a *turtle*, many parts of fishes of new genera, &c.

2816. *Keuper.* This formation of green, red, and purple sandstones and marls, is seen on a splendid scale at Stutgard, where it rests upon shell limestone, and is covered with *lias*. Calamites, and equisetaceous plants, resembling those of the *lias* and oolite of England, and also two new species of saurians (*cylindricodon* and *cubicodon* of Jäger) are found in it.

2817. *Lias.* The *lias*, marls and gryphite limestone, with many identical English fossils, are seen in Wirtemberg, the north of Bavaria, Hanover, Westphalia, &c. Six new species of *ichthyosaurus*, five of which are known in England; six or seven genera of fishes; two species of crustacea; eleven species of ammonites; twelve species of belemnites, scaphites, nautili, and numerous other shells common to the English *lias*, are found at Banz near Coburg, on the right bank of the Mayn. The *pentacrinites briareus* of the English *lias* is common; besides several species of corals hitherto unobserved in the *lias* of England.

2818. *Inferior oolite.* This is a great arenaceous deposit, generally highly ferruginous. In the gorge called the Porta Westphalica, by which the Weser escapes into the plains of Minden, there is a fine display of all the shales, sandstones, beds of oolite, &c., of which the inferior oolite is composed. It contains many characteristic British fossils, and in many places throughout Wirtemberg, Bavaria, Hanover, Westphalia, Franconia, &c., it caps the *lias*. The ferruginous sandstones of this formation are readily distinguished from those of the *lias* both by superposition and fossils.

2819. *Middle oolite, Jura limestone.* The mineralogical characters of the middle oolite of central and southern Germany are essentially different from those rocks of the same age in

Westphalia and Hanover; so that, instead of the shales, sandstones, &c., just described, they consist in one part of compact cream-coloured limestone, and in another of dolomite. In Franconia, so remarkable on account of the number of bears' caves in the hills opposite Banz, and in many other places, the dolomite usually caps the limestone, the latter containing the greater number of fossils. In these groups, and in the inferior oolite, there are many species of ammonite, and about sixty species of scyphia from the middle Jura limestone, and also many corals. At Solenhofen there are several quarries of a slaty or rather tabular compact limestone, which is valued as a lithographic stone. This Solenhof stone appears to be the equivalent to the Stonesfield slate of England, forming the uppermost part of the oolite formation in Germany, lying consequently immediately below the green sand. The higher members of the oolite group of England, viz., coral rag, Portland stone, &c., have not hitherto been met with in central Germany, though they may exist in Hanover.

2820. *Green sand.* This formation, wherever it occurs in Germany, is generally divisible, as in England, into lower or quartzey limestone, and upper or chalky sandstone; the former known in many districts as the *quader sandstein*, the latter as the *planer kalk*. Fine displays of these two rocks occur in southern Hanover and the northern flank of the Hartz, where the lower sandstone is sometimes a highly ferruginous rock; at other times, a white sandstone, in which character it ranges from the northern flank of the Hartz into Saxony and Bohemia. In Westphalia the green sand deposit is said to approach still nearer in characters to the English group.

2821. *Chalk.* This deposit, the newest of the secondary series, occurs in various localities in the great plain of northern Germany, in some points in the interior of the country; and deposits high in the Alps, with chalk fossils, as they have been called, are by many geologists maintained to be portions of the chalk formation, borne aloft during the upraising of these mountains.

2822. IV. *Tertiary rocks. Neptunian.* These rocks are considered as distributed in five great basins, the limits of which are thus designated:—

1. *Basin of Northern Germany*, bounded in some measure by the following towns:—Hanover, Wolfenbüttel, Magdeburg, Köthen, Halle, Merseburg, Zeitz, Gremma, Grossenhayn, Bunzlau, Strehlen, Niesse, Loislau, and Proskau; and extends further into Poland and Russia. Towards the north it terminates on the North Sea and the Baltic.

2. *Bohemian Basin*, bounded by the mountains that lie around Bohemia, as a great circular valley.

3. *Basin of the Rhine.*

4. *Bavarian and Upper Austrian basin*, including the tertiary plain of Swabia, Bavaria, and Upper Austria.

5. *Basin of Lower Austria and Hungary*, including the flat country of Lower Austria, and the great plains of Hungary.—These five basins or hollows, now filled with marine and lacustrine deposits, were formerly great inland seas, situated at different heights.

2823. *Plutonian secondary and tertiary rocks.* These are porphyries and traps of various kinds, which have been sent from below at different periods during the formation of the secondary deposits, and also in part so late as the formation of the tertiary rocks. Fulda, Saxon Erzgebirge, Hessa, and Bohemia, are rich in trap rocks. *Old volcanic rocks* also occur in different parts of Germany, especially in the neighbourhood of the Rhine.

2824. V. *Alluvial deposits.* These occupy great tracts of country, especially in the northern part of Germany.

SUBJECT. 2. *Botany of Germany, the Netherlands, and Poland.*

2825. *These are countries*, which, however interesting in themselves, do not afford any character so peculiarly striking in their vegetation as to render it necessary to dwell upon it here. As may be expected from their situation, the southern plants of the country, bordering upon the Gulf of Venice, partake of the nature of the Italian productions and the adjacent shores of the Adriatic. The midland parts yield a flora very similar to that of the middle and north of France; the mountains to that of Switzerland; while the northern parts bear a considerable affinity to England. Hungary includes mountains exhibiting a highly beautiful vegetation, and which has given rise to the splendid *Flora Hungarica* of Waldstein and Kitaibel; but the plants are more interesting to the botanist than to the general reader, and partake of an alpine character.

SUBJECT. 3. *Zoology.*

2826. *The zoology of Germany* is commensurate in importance with the wide extent of territory generally included under that name, and to the diversified nature of its surface. The lofty mountains and vast forests of Hungary, Bohemia, Poland, &c., give shelter to a much larger proportion of the native European quadrupeds, than is to be found, perhaps, in any other part of the Continent. The celebrated wild oxen of antiquity, the *Bos Urus*, if we may trust the zoological knowledge of travellers, appear to have existed in the Carpa-

thian forests within the last century, but it has long been extinct both there and in Lithuania. Bears, in former times, were very numerous, and are still asserted to be occasionally met with. The Wild Boar is not uncommon, and Wolves still less so; but the Chamois

CHAMOIS.

(fig. 371.), once common in Carniola and the Carpathian chain, is now rarely seen. This remarkable animal inhabits the wildest and most abrupt precipices, but does not ascend to those elevated heights which the Ibex alone delights to visit: it runs with rapidity along the most perpendicular ledges, springing across precipices, and bounding from rock to rock, with a steadiness and security truly wonderful. If pursued by the hunter beyond the means of retreat, it is said to pitch itself headlong downward upon its enemy, and dash him into the abyss below. Notwithstanding the wild nature of the Chamois, it has been sometimes known to mix with the domestic cattle and goats, and to be partially tameable.

2827. Some of the most formidable birds of prey belong to this part of Europe. The great cinereous Vulture (fig. 372.) (*Vultur cinereus* Lin.) is principally found on the lofty mountains of Hungary: it measures three feet six inches in length, and preys only upon dead animals; while the Imperial or Golden Eagle, plentiful in the forests, will devour its prey only when captured by itself. The Ringtail Eagle, scarcely inferior in size, is likewise met with. To these might be added numerous smaller species, uninteresting to the general reader.

VULTURE.

The great Black Woodpecker should not, however, be omitted, as being the largest of its genus known in Europe; nor is the rare *Picus canus*, or Grey Woodpecker, an uncommon inhabitant of the German forests.

2828. The most extraordinary reptile of Europe is the *Proteus anguinus*, an animal resembling a water-lizard, found in the celebrated lake Zirknitz, in Carniola. Naturalists were long divided in opinion, whether to consider it as a perfect animal, or the larva (or tadpole) of some other; but this latter supposition has since proved to be erroneous. It is, says Dr. Shaw, about twelve inches long, of a pale flesh-colour, and somewhat eel-

shaped; on each side of the breast are three branchial fins, or breathing organs, of a bright red colour: its eyes are stated to be remarkably small, and seated beneath the skin.

2829. The domesticated animals of Germany do not appear to have received that attention in their improvement which they require. The horses have never been in any great request, yet the breeds appear, to a certain extent, to have been ameliorated within the last hundred years. Most of the German princes have excellent horses in their studs; and their stallions are generally chosen from those of Arabia, Barbary, and Spain: from such sources greater results might have been expected. Yet the chief objection made to the German horses is that of being rather short-winded. (*Ham. Smith.*) The common breed of oxen have small or middle-sized horns; but the different polled races, or hornless cattle, now spread over Europe and part of America, would appear to have originated in Germany. The breeds of sheep are stated to be improving; those of Saxony and Bohemia, in particular, now furnish wool of a very superior quality.

SECT. III. Historical Geography.

2830. Ancient, or, as it was called, Great, Germany was known to the Romans, but not conquered by them. While the equally distant countries of France and Spain, and the remote island of Britain, were regularly incorporated into that vast empire, the ancient Germans never sacrificed any portion of their proud independence. They are described as having been the rudest, the fiercest, and the bravest of all the tribes of the barbarians. The country was almost entirely covered with vast forests, of which that called the Hercynian extended from the Rhine to the Vistula. Its surface is described by Tacitus and Cæsar as divided among a number of small nations, poor, hardy, and brave, scantily cultivating the ground, and despising all the arts of civilised life, led by their chiefs in war, but scarcely owning their authority in peace, and determining all things by a general assembly of the nation. Cæsar, Germanicus, Drusus, and other great captains, derived glory from their victories over the Germans, and penetrated even a considerable depth into their wilds; but the Romans never were able to form any permanent establishment, and considered themselves fortunate if they could preserve inviolate the boundary of the Rhine and the Danube.

2831. In the fourth century, the nations of Germany burst these barriers, and overwhelmed the sinking empire of the West. The Saxons over-ran Britain; the Franks, Heruli, and Burgundians seized different parts of France; the Lombards established themselves in

Italy; the Vandals and Goths penetrated into Spain and Africa. But while German nations thus swayed all the western kingdoms, they owned no dependence upon their original country, which remained in exactly the same state as before she sent forth these numerous bands of conquerors.

2832. *Under the reign of Charlemagne*, Germany first felt the weight of conquest, though only by the arms of her own children. That great monarch spent nearly his whole life in quelling the continual rebellions of the Saxons; but he succeeded in placing on his head the imperial crown, which conferred dominion over France, Germany, and Italy. Under the weak and divided sway of his posterity, this great dominion fell gradually to pieces; but the name and character of an empire remained attached to Germany; and the German emperors always considered themselves as successors of Charlemagne.

2833. *The division of the empire into feudal states* took place gradually, as the central power became weaker, and the dukes, landgraves, and other nobles were emboldened to shake off the yoke. At length they carried the spirit of independence to a higher pitch than in any other of the western kingdoms, rendering the empire itself elective. Nine of the great princes temporal and spiritual,—the king of Bohemia; the dukes of Bavaria, Saxony, Brandenburg, and Hanover; the Palatine of the Rhine; the Bishops of Mentz, Trèves, and Cologne,—exercised this power, and assumed the title of electors. The empire thus passed successively into the houses of Saxony, Franconia, Bavaria, and Austria.

2834. *The rise of the house of Austria*, in the thirteenth century, under Rodolph of Hapsburg, forms a memorable era; that house having ever since (except during a very short interval) retained the succession to the empire, though always with a form of election. Its power, however, has rested much more upon its actual possessions, and the warlike character of its subjects, than upon any jurisdiction which its sovereigns have possessed as emperors.

2835. *The Reformation* formed a remarkable era in the history of Germany. Originating in that empire, it was soon embraced by a great proportion of the leading states, and was accompanied, as usual, with bold and sometimes republican opinions on the subject of government. The emperors put forth their whole strength in endeavouring to crush it by force of arms, and at the same time sought to establish their paramount dominion over all Germany. The perseverance of the protestant confederacy, and the glorious victories of Gustavus Adolphus in the thirty years' war, not only established freedom of worship, but emancipated the smaller states from the authority of the emperor, and rendered his supremacy over the Germanic body little more than an empty name.

2836. *The rise of Prussia*, in the middle of the eighteenth century, caused a considerable change in the political aspect of Germany. Amid all the independent states, Austria had alone ranked as one of the first magnitude, and had thus maintained a paramount influence. Prussia, however, having wrested from her Silesia, and obtained accessions in other quarters, was enabled to treat with her on equal terms; and though Austria continued still a great state, her power over the Germanic body was almost annihilated.

2837. *The French revolutionary war* caused a mighty movement. The whole western part of the empire was new-modelled, under the title of the Confederation of the Rhine; and Prussia and Austria became little more than vassal states. A mighty reaction, however, ensued; France was driven completely within her former boundaries, and Germany, with some modifications, was replaced in the same situation as at the commencement of this terrible contest. An attempt has even been made to revive the powers of the Germanic diet: these have been chiefly employed by the great states in dictating, to those of inferior note, measures regarding the defence of the empire, and the regulation of the press and the universities.

SECT. IV. *Political Geography.*

2838. *The political system of Germany* is particularly complicated, chiefly through the great number and variety of the states of which it consists, partly also through the common bond of union which is attempted to be maintained among them. It will therefore be requisite to consider, first, the Germanic body, as represented in the Diet, which is entitled to exercise certain general functions; and, next, the political form, power, and relations of the particular states.

SUBSECT. 1. *Germanic Body.*

2839. *The Diet* has for its office to preserve the external and internal security of Germany, as well as the independence and safety of its particular states. It professes to regulate all the foreign relations of the empire, and the disputes which may arise between one state and another, without interfering with the interior administration of any.

2840. *The Diet consists* of deputies from each particular state. The number of votes possessed by each varies, according to its extent and power, though not in any exact or uniform proportion. In the full meeting the aggregate number of votes is seventy, which are thus distributed:—Austria, Prussia, Saxony, Bavaria, Hanover, and Wirtemberg, have each *four*, Baden, Hesse-Cassel, Hesse-Darmstadt, Holstein, Luxemburg, each *three*; Brunswick,

Mecklenburg-Schwerin, Nassau, each *two*; all the rest, Saxe-Weimar, Saxe-Gotha, Saxe-Coburg, Saxe-Meiningen, Saxe-Hilburghausen, Mecklenburg-Strelitz, Holstein-Oldenburg, Anhalt-Dessau, Anhalt-Bamburg, Anhalt-Köthen, Schwartzburg-Sondershausen, Schwartzburg-Rudolstadt, Hohenzollern-Hechingen, Lichtenstein, Hohenzollern-Sigmaringen, Waldeck, Reuss old and new, Schaumburg-Lippe, Lippe-Detmold, Hesse-Homburg, Lubeck, Frankfort, Bremen, Hamburg, have each only *one*. Several of these belong to foreign sovereigns, who have a vote in virtue of territories which they hold in Germany, and are subject to the Diet in matters relating to those territories; as the king of Great Britain for Hanover, the king of Holland for Luxemburg, the king of Denmark for Holstein. The full assembly of the Diet resolves itself into a smaller assembly or committee of seventeen, in which only the great powers have each a vote, and the other votes are respectively assigned to two, three, or four of the smaller powers united. This committee prepares all the business of the full Diet, and puts it in a form to be voted upon. The sittings of the Diet are perpetual, though, when all their business is disposed of, they may allow themselves a vacation of not more than four months.

2841. *The emperor of Austria* no longer claims his ancient prerogatives as emperor of Germany, of which title he was divested by Napoleon; he professes himself only *primus inter pares*; but he is president of the Diet, and submits to it the subjects on which it is to deliberate. He cannot, however, withhold propositions made by any other members, but must bring them forward in proper time and place. He has also a casting vote in the committee. There being no longer an emperor, the functions of the nine electors have ceased.

SUBSECT. 2. *The Austrian Empire.*

2842. *The empire of Austria* is not only the first power in Germany, but by its possessions, both within and without, it has long ranked among the foremost states in the general system of Europe. By the last war, indeed, it lost the Netherlands, a rich and important territory, though too much detached from the rest. But by means, lawful or unlawful, it obtained accessions which were nearly an equivalent; and its possessions are now formed into a vast, connected dominion in the centre of Europe. In Germany, they comprise Upper and Lower Austria, Bohemia, Moravia, with the Alpine regions of Styria, Carinthia, and the Tyrol; in Poland several provinces, which have been wrested by successive partitions, and to which it gives the name of Gallicia; the entire kingdom of Hungary; and, in Italy, Venice, Milan, Mantua, and other territories, which have been united under the name of the Lombardo-Venetian kingdom. The German territories, with Hungary, are known under the appellation of "the Hereditary States." The Austrian monarchy is bounded on the east by those of Turkey and Russia; on the north by those of Prussia and Saxony; on the west chiefly by Bavaria, Switzerland, and Piedmont; on the south by Tuscany and the Ecclesiastical States. The whole territory amounts, according to Lichtenstein, to 268,500 square miles. The number of inhabitants, in 1815, was reckoned by Blumenbach at 28,182,336; by Lichtenstein at 27,617,500.

2843. *The following* is Professor Bohrer's estimate of the *extent and population* in 1826, to which we add the population in 1829, according to Col. Traux:—

	Square German Miles.	Cities.	Towns.	Villages.	Houses.	Population.	
						1826.	1829.
Lombardy	851.94	42	281	5,401	542,543	4,237,301	4,279,764
Dalmatia	273.75	9	14	988	49,175	323,112	329,727
Tyrol	516.41	21	32	1,558	98,689	789,835	776,390
Illyria	519.74	54	57	6,848	167,012	1,121,240	1,138,506
Styria	399.40	20	96	3,539	163,050	824,505	839,128
Austria	708.65	52	352	11,126	274,997	2,008,970	2,031,136
Bohemia	952.95	286	275	11,924	541,074	3,698,506	3,748,361
Moravia	481.56	119	178	3,673	288,905	1,968,713	1,994,850
Gallicia	1548.03	95	194	6,042	633,709	4,293,488	4,385,608
Hungary	4181.60	62	644	11,695	1,026,007	9,471,263	9,659,686
Transylvania	1100.80	13	64	9,566	256,629	2,000,015	2,027,566
Military Frontier	609.70	12	13	715	89,669	907,453	923,315
	12,144.53	785	2200	73,075	4,131,959	31,664,401	32,134,037

2844. *Of these*, according to Lichtenstein, 4,800,000 are Germans; 11,750,000 Slavonians; 4,000,000 Magyars, the ruling people in Hungary; 4,500,000 Italians; the rest Wallachians, Jews, gipsies, Greeks, and Armenians. In regard to religion, about 22,000,000 are Roman catholics; 3,000,000 Greek; 2,000,000 Protestants; 500,000 Jews. If we except the mountain borders, the whole empire enjoys the happiest climate, and is fitted to produce corn, wine, silk, and other valuable articles in the highest perfection. Except however, Lombardy, part of Bohemia and Silesia, and the Alpine tracts, cultivation is nowhere carried to the height of which it is susceptible. This

seems owing partly to the proud indolence of the Austrian and Hungarian population; partly to the obstructions which stand in the way of foreign commerce; for there is no sea-coast unless at the head of the Adriatic; and the great rivers which roll through the territory, have afterwards a long course through that of foreign and partly semi-barbarous states, before they reach the sea.

2845. *For the same reasons*, none of the Austrian dominions are *manufacturing countries*, though in all those north of the Alps linen is fabricated to a great extent. But the mineral riches of the Austrian dominions are equal or superior to those of any other country in Europe. The salt mines of Poland are the most extensive in the world; the others rank as to importance in the following order: iron, copper, silver, gold, cinnabar, quicksilver, lead, tin.

2846. *The government* of Austria is an hereditary monarchy, almost entirely absolute. Originally the monarch enjoyed the title of emperor only when elected as head of the Germanic body; and his hereditary titles were archduke of Austria, king of Hungary and Bohemia. But when Bonaparte compelled Francis II. to resign the title of emperor of Germany, he assumed in its stead that of emperor of Austria.

2847. *There are assemblies called States* in all the countries subject to Austria, except Friuli and the military limits. But in general they impose no check on the prerogative of the monarch; and their assemblage is only for form's sake, or for giving assistance in some secondary branches of administration. In Hungary and Transylvania, however, the states have a share in the making of laws, and possess other important prerogatives; and in the Tyrol no new tax can be imposed without their consent. Hungary and the Tyrol, accordingly, though the most troublesome in peace, have in war proved always the bulwarks of the Austrian monarchy. The Hungarian government, however, is entirely aristocratical, the body of the peasants being in a state approaching to personal bondage. This was the case also in Austria and Galicia till 1781, when slavery was abolished by Joseph II. The states consist of four orders, clergy, nobles, knights, and representatives of the free cities. In the Tyrol alone there is a house of peasants.

2848. *Justice* is administered in Austria according to recent codes, which were formed by Joseph II. in 1786-7, and by Francis II. in 1811-12. The tribunals of the first resort are conducted, not by salaried judges, but by the magistrates of towns; and in the country by courts composed of the privileged nobility of the district. From them an appeal lies to colleges of justice established in the capital of each province.

2849. *The finances of Austria* are involved in considerable obscurity, as no official statements on the subject are ever made public. In 1819, Hassel calculated the entire income at 125,000,000 florins, about 13,100,000*l.* sterling. Of this the proportion was from Upper Austria, 19,800,000 florins; Lower Austria, 5,200,000; Salzburg, 800,000; Styria, 6,000,000; Carinthia, 2,500,000; Carniola, 2,200,000; Littorale, 2,000,000; Tyrol, 4,500,000; Bohemia, 19,500,000; Moravia and Silesia, 8,000,000; Galicia, 10,000,000; Hungary, 20,000,000; Transylvania, 5,500,000; the military limits, 500,000; Dalmatia, 500,000; Lombardy, 9,000,000; Venice, 9,000,000. This revenue arises, 1. from land-tax, which, for the whole empire, may amount to about 41,000,000 florins. 2. The customs, duties on commodities, stamps, and lottery, not reckoned at more than 30,000,000. 3. The royal monopolies; a copious source, which yields at present not less than 36,000,000. 4. The imperial domains, the value of which is estimated at 300,000,000, but the net revenue arising from them at not more than 7,000,000 or 8,000,000. There are also particular domains in Hungary and Transylvania, which yield about 2,000,000 more. The expenditure is involved in still greater uncertainty. The military disbursements are undoubtedly on a more extensive scale than the revenue can well support, though Hassel rejects as extravagant Lichtenstein's estimate of 140,000,000. The expenses of the court and civil establishment are estimated at 54,000,000, besides which there are the private expenses of the monarch, regulated entirely according to his pleasure.

2850. *The Austrian military establishment* consisted, in 1819, of 270,000 men; 185,400 infantry, 38,400 cavalry, 17,800 artillery, 2350 engineers; of pioneers, invalids, the transport service, &c., 20,600. These are augmented in war by the militia called the *landwehr*; which in 1811 were, for Bohemia, 21,590; Moravia and Silesia, 11,770; Austrian circles, 10,000; Styria and Clagenfurt, 6650; and for Galicia, 21,500: making in all, 71,510; but the amount is now supposed to have reached 100,000. Besides these, there is the Hungarian levy, called often the *insurrection* levy, led by the nobles, who in the seven years' war replaced Maria Theresa on the throne, and who in the last war repeatedly came forward in great force. In 1797 they mustered 35,000 foot and 18,000 horse. Austria has an excellent body of cavalry, both of heavy dragoons for charging in the field, and of light irregular bands of Croats, Pandours, and other tribes from the military frontier. Her infantry is also respectable: there is something inert, however, both in her councils and movements, which has usually made her unfortunate in her wars, both with France and Prussia; yet she has always recruited her strength with surprising rapidity from the resources of her warlike population.

2851. *Though a maritime force* is ill suited to the situation of Austria, yet she has formed a small navy at Venice, consisting of three ships of the line, two frigates, and twenty-four sloops; and she maintains an armed flotilla on the Danube.

SUBSECT. 3. *Kingdom of Prussia.*

2852. *The kingdom of Prussia*, which at the beginning of the last century had neither name nor place among the states of Europe, has by rapid advances become one of its most powerful monarchies. The basis was formed by the territory of Brandenburg, the ruler of which ranked as elector, and was one of the chief of the second-rate princes of the empire. About the beginning of the seventeenth century, the elector acquired the Grand Duchy of Prussia, a territory held for some time by the knights of the Teutonic order, who being unsuccessful against the Turks in Palestine, turned their efforts to the conversion and conquest of the northern borders of Europe. The united state, however, did not make any great figure till the middle of the seventeenth century, when Frederick I. not only assumed the title of king, but spent his life in forming an army, and raising its discipline to the highest pitch. This army devolved on his son, the great Frederick, whose daring and enterprising spirit was not long of employing it in the extension of the monarchy. From the house of Austria he wrested Silesia, one of the finest of its provinces. By the partition of Poland, an iniquitous proceeding, in which he seconded Catherine, he not only extended, but connected together, many of his scattered possessions. In 1806, the battle of Jena seemed to have for ever prostrated the monarchy; but the disastrous campaign of the French in Russia, and subsequently the patriotic and universal rising of the people, completely expelled the usurping power, and not only re-established the kingdom in its ancient rights and possessions, but acquired several new provinces.

2853. *The parts of the Prussian monarchy* are so various and detached, that it is difficult to connect them under any general view. In Germany, she has the entire territory of Brandenburg, by far the greater part of Silesia, and Pomerania, of which Sweden is now entirely stripped. Her Saxon possessions consist of Magdeburg, Merseburg, and Erfurt. In Westphalia, she has Minden, Münster, and Arensburg; on the Rhine, Düsseldorf, Cologne, Clèves, Coblenz, and Triers. East of Germany, she has the duchies of East and West Prussia, from which she takes her name. In Switzerland, she has the principality of Neuchâtel; and in Poland that of Posen. The two Prussias, with Posen and the eastern German provinces, form nearly a connected territory, which comprises the main body of the monarchy. The Westphalian and Rhenish provinces form a detached western portion, separated from the rest by Hanover, Hesse, and Saxony.

2854. *The following table* exhibits a compendious view of the extent, population, &c. of the different provinces of the Prussian monarchy in 1831, and of the regencies into which the provinces are subdivided:—

Provinces.	Regencies.	Square Miles, 15 to a Degree: about 22 English.	Population, including the Military.	Square Miles in the Provinces.	Population in each Province.	Number of Inhabitants to the Square Mile.
Prussia	East	1 Königsberg	405.70	1,168.73 of which } 42.64 in lakes. }	2,008,561	1,783
	West	2 Gumbinnen	297.07			
		3 Dantzic	150.90

		22 Düsseldorf	98.90			
Neufchâtel		23 Coblenz	109.43	15.95	54,000	3,856
		24 Trèves	120.99			
		25 Aix la Chapelle	75.41			
Total				5,054.68	12,780,773	

2855. *The productions* of this large territory are as various as its constituent parts. According to Hoffmann, the total area is 107,765,000 Magdeburg acres. Of these, 42,767,000 are arable; 432,000 garden ground; 54,000 vineyard; 20,436,000 pasturage; 25,754,000 woods; 18,322,000 rock, water, and waste. The annual revenue derived from it is calcu-

lated as follows:—Arable, 50,656,000 rix-dollars; pasturage, 19,652,000; woods, 6,500,000; gardens, 2,782,000; wines, 300,000; fishery, 749,000; hunting, 745,000: in all, 81,304,000 rix-dollars. The capital value is estimated at 2,032,600,000 rix-dollars. Prussia is not, on the whole, a manufacturing country, though the linens of Silesia are highly distinguished, its woollen manufacture is also extensive, and Berlin has some fine fabrics of glass and porcelain. In 1805, the whole manufactures of Prussia were valued at 84,790,000 rix-dollars, which were supposed to give employment to 350,000 persons.

2856. *The constitution of Prussia* has long been what we in England would call a pure military monarchy; but the king is, notwithstanding, very far from being absolute: his prerogative is limited by the privileges enjoyed by the different orders of his subjects, and still more by their intelligence and power. The king of a country in which every man is a soldier, and every man is well educated, though he may not govern through the medium of parliaments or states, must act in a constitutional manner; and cannot venture on a course of policy decidedly in opposition to the opinions of his subjects. The provincial states, organised since the peace, have a considerable degree of power: and it is not to be doubted that Prussia has been, since 1815, one of the most tranquil, best governed, and most flourishing countries of Europe.

2857. *Education in Prussia.*—The great glory of Prussia is her admirable system of public instruction. It was first introduced into Silesia by Frederick the Great, after the conquest of that province; and has since been gradually extended to all the other parts of the monarchy. Attendance at school is not optional, but compulsory. Every child, whether male or female, from the age of seven to fourteen years complete, must either regularly attend some public school, or its parents or guardians must satisfy the public authorities that it is properly instructed at some private establishment. The fees are moderate; and the children of such poor persons as are unable to afford them are instructed gratis. All the elementary branches of instruction are taught according to the most improved methods. No particular religious system is inculcated in the schools; but at certain specified periods the children receive religious instruction from the ministers of the different persuasions to which their parents belong. Of the total population of the kingdom in 1831, amounting to 12,780,773, the Prussian statisticians calculate that 2,043,000 were children from seven years of age to fourteen complete; and the official returns from the different schools in the same year show that this number was actually at school! Hence it follows, that there is not in Prussia a single individual, of either sex, or of any condition in life, who does not receive what is really an excellent education. Considered in a general point of view, it is as superior as can well be imagined to any thing that exists in this country. Normal schools are established in the different provinces for the instruction of the masters and mistresses; and no one is intrusted with the charge of a school, who, besides possessing information, has not also given proofs of his capacity to teach, and of his acquaintance with the best methods of teaching. The Prussian system has, we are happy to say, been adopted in several other German states. Wirtemberg, Bavaria, &c. have now organised systems of elementary instruction, that ensures to every individual the inestimable advantage of a good education. The reader desirous of further information as to the origin, progress, and present state of education in Prussia and Germany, will find the requisite details in *Adams's Letters on Silesia*, and in the *Report*, by M. Cousin, to the French government, on the state of education in Germany.

2858. *The taxation of Prussia* is large in proportion to its population, owing in a great measure to the supposed necessity of maintaining an army sufficient to cope with neighbours of more extended dominion. The entire revenue in 1816 amounted to 76,000,000 florins (7,980,000*l.*). Of these, East Prussia produced 8,100,000; West Prussia, 3,750,000; Posen, 3,100,000; Brandenburg, 9,000,000; Pomerania, 3,000,000; Silesia, 13,500,000; Saxony, 10,417,000; Westphalia, 8,431,000; the Rhine, 15,670,000.

2859. In 1829, the receipts were stated at 50,796,000 rix-dollars (about 8,889,000*l.*). The following were the chief sources:—Domains and forests, 5,524,000; mines, 1,000,000; posts, 1,100,000; lottery, 684,000; monopoly of salt; 4,783,000, land-tax, 9,657,000; income tax, 6,368,000; licences, 1,736,000; customs and excise, 18,733,000. The expenses come chiefly under the head of public debt, 10,937,000; pensions, 3,158,000; war, 22,165,000; foreign affairs, 586,000; the interior, 4,883,000; ecclesiastical and medical affairs, 2,347,000; justice, 1,823,000; provincial administrations, 1,830,000.

2860. *Prussia* has contracted less debt than most modern states. Frederick the Great even left behind him a considerable treasure; but his successors incurred a debt of 60,000,000 or 70,000,000 rix-dollars. This debt, Frederick-William III. by a strict economy, had in a great measure paid off, before the battle of Jena; but since that time the exigencies of the monarchy have caused the accumulation of a large funded debt, which, including the foreign loans, amounts to 160,000,000 rix-dollars (25,200,000*l.*), besides a floating debt of 18,000,000 or 20,000,000.

2861. *The army*, for its high discipline and fine condition, has been always the pride of the monarchy; and, notwithstanding the blow it received at the battle of Jena, its glories were in no long time completely revived. The army, as formed by Frederick I., was distinguished chiefly for that rigid discipline which reduced the soldier almost to the level of a machine moved at the will of his officer. This system became the object of imitation to the other states; but the victories of the French showed that greater things might be done by a more active and intelligent soldiery. The Prussian force consists at present of three parts: the standing army, the *landwehr*, and the *landsturm*. The former is composed of 165,000 men, of which 18,220 are guards; 112,140 infantry; 19,232 cavalry; 15,408 artillery and engineers. They are recruited by conscription from the class of young men between twenty and twenty-five, who are all liable to be called upon for three years' service. Various opinions may be entertained as to the merit of this system. It may, however, be observed, that the universality of the conscription lessens the sense of the hardship which it inflicts; while it has the incontestable advantage of identifying the military force with the nation. The *landwehr* consists of those who have escaped the conscription, of those who have retired from the army, and of all others under forty years of age. They consist of two *bans*; the first comprises all who have not served, or are under thirty; the second, those who have retired from the line, or who are under forty. They serve constantly in war; but in peace only during a part of the year, when they are called out to be trained. In the former case, only the first ban takes the field with the regular army; the second remains at home to perform garrison duty. The *landwehr* consists of 160,000 men; making the whole war establishment, 325,000. The first ban amounts to 95,000; so that 260,000 is the amount which the king can call at once into the field. The *landsturm*, consisting of all not included in the preceding classes, serves only during war; yet not against the enemy, being occupied solely in maintaining internal peace and security.

2862. *A maritime force* has never been an object of attention in Prussia; but she possesses a considerable extent of sea coast, and some of the most important harbours in the Baltic. In 1831, there belonged to Prussian owners 652 merchant ships, of the burthen of

76,987 lasts, or 115,480 tons, being a greater amount of tonnage than is possessed by Ireland; and there is every reason to think, considering the rapidly improving state of manufactures and commerce in Prussia, that her shipping will continue to increase.

SUBSECT. 3. *Smaller States.*

2863. *The numerous states into which the German confederation is divided have all internal arrangements peculiar to themselves. Only the constitution of the leading states will here be delineated, leaving any peculiarities in the minor ones to be noticed in the local section.*

2864. *Bavaria, long the second, is now the third state in Germany: she was once the successful rival of Austria, and as such beheld her princes seated on the imperial throne. Napoleon, in the view of employing the elector against the house of Hapsburg, greatly augmented his dominions, and invested him with the title of king. As he ruled him, however, with a rod of iron, the new king seized the first opportunity of joining the confederacy against the French emperor; in virtue of which, though obliged to restore the Tyrol and Salzburg to Austria, he received elsewhere an ample compensation. Bavaria now possesses a territory of 1437 German, or about 53,000 English square miles, which in 1826 was divided and peopled as follows:—*

Circles.	German Square Miles, 15 to a Degree.	Population.	Catholics.	Protestants.	Jews.
The Iser - - - - -	286	581,923	572,715	8,237	702
The Regen - - - - -	198	419,949	396,248	22,875	716
Upper Danube - - - - -	182	505,220	463,854	36,512	4,538
Lower Danube - - - - -	155	407,541	406,001	1,520	11
The Rezat - - - - -	148	539,039	118,408	405,939	14,706
Upper Mayn - - - - -	198	523,789	267,885	249,290	6,602
Lower Mayn - - - - -	170	542,475	438,260	86,656	17,301
Rhine - - - - -	100	517,081	217,012	283,640	12,998
Total - - - - -	1,437	4,037,017	2,880,383	1,094,669	57,574

The king, in 1818, fulfilled his promise of giving his people a government moderately constitutional. The states consist of two chambers: the first is composed of the princes, the high nobility, and the heads of the church; the second, of deputies from the smaller landholders, the cities, the minor clergy, and even the universities. They meet only once in three years; but they enjoy the full privileges of such a body; since no new law can be passed, no new tax imposed, without having first been voted by them. The revenue of Bavaria amounted, in 1830, to 29,200,000 florins (3,050,000*l.*), of which 5,800,000 arose from land-tax; 3,000,000 from house and other direct taxes; customs, 2,000,000; excise, 4,600,000; 2,000,000 from forests; 7,000,000 from royal domains and rents; 2,000,000 from mines and salt monopoly; 352,000 from the post-office; 1,200,000 from the lottery. The expenditure amounted to 29,200,000 florins; of which 3,005,000 were for the royal house and court; 8,000,000 for the army; 1,250,000 for religion; 1,270,000 for roads and bridges; 750,000 for public instruction; 1,240,000 for ministry of the interior; 1,708,000 for justice; 152,000 for public health; pensions, 4,500,000; public debt, interest, and sinking fund, 8,355,000. The regular army consists of 46,341 men: of which 29,232 are infantry of the line, and 7334 light infantry; 6408 cavalry; 3357 artillery. There is also a reserve to fill up the ranks of the regular army, and a *landwehr* for internal defence.

2865. *Saxony* always ranked as one of the most powerful of the German electorates, until the ascendancy gained by Prussia. The elector of Saxony received from Napoleon not only the title of king, but an addition of territory doubling that which he formerly possessed. He adhered to the last to that once powerful benefactor, on whose fall he was not only stripped of all the newly acquired territories, but obliged to surrender some of his former possessions. The extent of his present dominions is only 7276 square miles; but the population being very dense, amounts to 1,232,000 inhabitants. The government is not quite absolute, but has old feudal states, which must concur in the making of laws and the imposition of taxes. As they represent, however, only the privileged orders and the corporations, the peasantry and small proprietors are entirely thrown out, and have to bear an unequal share of the public burdens. The revenue is now computed at 11,000,000 florins; the debt 36,000,000. The army, which in 1813 contained 37,000 troops, is now reduced to 10,000, with a reserve, however, of the young men, between the ages of eighteen and thirty-one, who may be called upon to recruit its ranks.

2866. *Wurtemberg*, originally a secondary German state, owed its aggrandisement and its kingly rank to Napoleon, and has been allowed to retain both. It contains 7920 square miles, with a population, in 1816, of 1,411,000. Wurtemberg has taken the lead among the

constitutional states of Germany. On the 3d of May, 1817, the king granted a charter, by which the states, composed of two chambers, the nobles and the commons, are to be assembled every two years, and to possess all the privileges enjoyed under the best regulated limited monarchies. The king has a revenue of 9,224,000 florins, which somewhat exceeds the expenditure, but is burdened with a debt of 27,000,000. He maintains an army of 12,000 infantry, 3600 cavalry, and 2500 artillery.

2867. *The other principal states* belong to monarchies out of Germany, of which they are only appendages.

2868. *Hanover*, on the accession of its elector to the throne of Great Britain in 1714, saw this title and that of Brunswick-Luneburg merged in the greater name conveyed by this inheritance. It has always, however, been held as politically a foreign country. The Hanoverian has not the rights of a Briton, nor the Briton those of a Hanoverian. Britain may make war with all the world, and Hanover remain in profound peace. The converse of this proposition has not been found practically true, and Hanover has frequently drawn this country into the vortex of continental war and policy. The kingdom of Hanover has an extent of 15,180 square miles, and a population of 1,550,000. There are provincial states in its several districts, and also a general assembly of the states, which shares with the sovereign the power of making laws and imposing taxes. The elections to the lower chamber, however, are made by the magistrates, who are themselves often elected in a manner independent of the citizens. The revenue is 10,800,000 florins, with a debt of 26,000,000, which causes an annual expense of 1,200,000. The army consists of 12,940 men, of whom about a third are cavalry; besides a *landwehr* of 18,000.

2869. *Of the other smaller states*, Holstein and Luxemburg are so incorporated, the one with Denmark and the other with the Netherlands, as to be politically identified with them. Those smaller states which remain entirely German will be considered under the section of local geography.

SECT. V. *Productive Industry.*

2870. *The products of the industry of Germany*, an extensive region cultivated by a laborious people, are of large amount. They consist of plain, solid, somewhat rough articles; in exchange for which, she procures the finer manufactures of England and France, and the delicate productions of southern Europe and the Indies.

2871. *Agriculture*, throughout all this fertile region, is carried on with great diligence, though not altogether on the extensive scale, or with the intelligence, which have rendered British farming so successful. The cultivators are mostly little farmers or little proprietors, who till the ground with their own hands, and who, in all the Teutonic states, constitute a class called *bauer*, or peasants, to which we have nothing exactly corresponding. The improved processes of this important art, however, are making their way, though slowly. The plough is the universal instrument of cultivation, except in some of the mountain tracts of Salzburg and the Tyrol, where the spade is used. The horse in the north, and the ox in the south, are chiefly employed in tillage. Field after field spreads usually in an apparently boundless expanse, except in some parts of Westphalia and Holstein, where hedges are interposed to divide them.

2872. *Of the various kinds of grain*, rye is the most extensively cultivated, and forms the food of the great body of the people. Wheat is also raised largely, and is of excellent quality, especially in Bavaria and Austria; buckwheat is sown chiefly on the sandy tracts of northern Germany. Barley and oats, of various kinds, are also general; and maize abounds in Moravia and the extreme southern districts. Peas, beans, lentils, and other pulse are produced in great abundance, and great quantities are sent out from the northern parts. Generally speaking, Germany is a corn-exporting country; for though Lower Austria receives grain from Hungary, and Silesia from Poland, yet this is not nearly equal to the quantity conveyed from Swabia and Franconia into Switzerland, and from the northern parts to Sweden, and also to Great Britain, when she will admit it. Garden vegetables are reared most sedulously, and in great perfection; the cabbage in particular, in the form of *sauer kraut*, is an object of exportation. Other useful articles are not wanting. Flax is raised in such immense quantity, that though it be the material of the staple and universal manufacture, there remains a surplus to be exported. Hops, a native German plant, are produced, especially in Bohemia and along the Mayn, in quantities more than sufficient for internal consumption. Rape is also a production peculiarly German, and vast quantities of rape oil are used both in manufacture and for lamps. Much oil is also expressed from other vegetable substances; yet, as Germany does not produce the olive, she is obliged to import both from southern Europe, and from the countries which participate in the northern whale-fishery.

2873. *Germany enumerates wine among her products*, though not in the first class. All her southern districts, as far as the 51st degree, produce it; but only the hard, cold, agreeable wine, peculiar to the banks of the Rhine, and called Old Hock, is in

much request abroad. Hassel reckons, however, that the country produces 12,000,000 eimers; of which quantity 4,500,000 are raised in Austria, the rest on the Rhine and its tributaries. This amounts to only one half of what Hungary, and one sixth of what France produces. It does not obviate the necessity of an extensive importation from France, Spain, and Hungary. The wine made on the Elbe and the Oder is of little use, except for vinegar.

2874. *In respect to live stock*, the peculiar eminence of Germany consists in the hog, of which Hassel computes that 8,000,000 are annually slaughtered. Pork is, indeed, the most favourite food of the Germans, who, notwithstanding its abundance, even import quantities from Hungary and Turkey. On the other hand, Germany has a large export trade to France and the Netherlands, both of live hogs and of hams and sausages; nor does any ship touch at the northern ports without taking in a stock of these German supplies. Horned cattle also form the chief branch of rural industry in the mountainous districts of the south, Bavaria, Swabia, and the Tyrol. In the great northern plain they are used chiefly for labour, except in East Friesland, Holstein, and other marshy tracts, where they yield milk more abundantly than the hill-cows of the south, but it is of inferior quality. Cattle are imported from Poland and Hungary, but not nearly to such extent as the salted and dried meat exported to other countries. Hassel estimates the collective number of the oxen, cows, and calves of Germany at from 12,000,000 to 14,000,000. According to positive enumerations, excluding calves, the proportions are, for Austria, 2,600,000; Prussia on this side the Elbe, 1,328,000; Saxony, 710,000; Westphalia, 508,000; Wirtemberg, 600,000; Baden, 333,000; besides a great part of the empire in which no account has been taken. Germany is supposed to contain nearly 2,000,000 horses, which are not handsome, but well-built, strong, and useful. They are particularly adapted for heavy dragoons, and for that purpose are sent into France and the Netherlands; but the German states cannot keep up their light cavalry without importation from the eastern countries. Sheep are numerous, not in the southern, but chiefly in the middle states, as Silesia and Saxony. The wool has been so much improved by crosses with merino and other breeds, as to have superseded the importation of Spanish wool, and even to have, in a great measure, supplanted it in the British market. There are supposed to be 20,000,000 sheep in Germany. Prussia numbered 3,768,000 after a war which had diminished her flocks by a full third. Bees'-wax and honey were a great ancient staple commodity of Germany; but since sugar has been introduced, and the Reformation, by diminishing the consumption of candles in churches, has reduced the demand for wax, this staple has greatly fallen; yet Lusatia, Luneburg, and some other districts, produce more than is wanted for Germany itself.

2875. *The forests of Germany* are very noble, and are supposed to cover not less than a third of its surface. They are of every description, and for every use. It is complained, however, that, of late years, great neglect, combined with profuse consumption of wood, either for luxury or manufacture, has considerably diminished the abundance of this article, which has risen in many places to six, eight, or even ten times its former price. Still a great quantity is carried down the rivers to the Netherlands and Britain, and pot and pearl ashes are made in the forests. Recently, the German princes, considering that the mines and many of the manufactures absolutely depend on a supply of wood, have made regulations to prevent its wanton consumption, and to ensure fresh plantations. They have even formed institutions, and founded lectures in the universities, for teaching the management and promoting the growth of wood; so that there is, perhaps, no country in which so much is done for securing to posterity a supply of this valuable article.

2876. *In manufactures*, Germany does not retain that prominent place which she once held. Formerly the Hanse towns clothed all the north; but since the spirit of industry has been awakened, first in Holland, then in Britain, and lastly in France, Germany, instead of supplying those countries, has been inundated with their fabrics, and can scarcely maintain the superiority of her linens. Even this is a recent branch, introduced by the exertions of Frederick the Great and Joseph II. A great temporary impulse was given by Napoleon's continental system, under which all importation from Britain was prohibited. Cotton, in particular, then rose into extraordinary activity, and the whole Erzgebirge became one cotton factory. After the general peace, however, and the opening of the European markets, this artificial industry was found incompetent to sustain the rivalry of the British, whose superior skill and machinery enabled them to undersell the Germans in every market. On the other hand, Ireland had availed herself of the cessation of German rivalry to undertake the supply of linen to the colonies, the best market for that article. She made great progress also in the culture of flax, and the spinning of linen yarn, both which commodities the British manufacturers had been accustomed to import from Germany. That country thus not only lost the extraordinary impulse which its manufactures had received, but saw them reduced to a more depressed state than had been known at any former period.

2877. *Linen, one of the staples of Germany*, has its chief seat in Silesia, where many very fine fabrics are produced, and where the entire produce is estimated at upwards of 1,500,000*l.*;

in Bohemia, where it is supposed to be of little less amount; and in Lusatia. Coarse linen is fabricated in Prussian Westphalia, Hanover, Brunswick, and Hesse-Cassel. The woollen manufacture is very flourishing; and Germany is now, in a great measure, independent of foreign supply. Its principal seats are in the Prussian territory of Aachen, in Moravia, Bohemia, Silesia, Lusatia, and Saxony. Leather is produced in sufficient quantity to leave a surplus for exportation. The branches in which Germany excels are leather breeches, gloves, and every thing that relates to military equipment. Earthenware has been carried to great perfection. The porcelain of Meissen, Berlin, and Vienna, surpasses every thing of the kind in Europe, and in some respects even excels that of China. German tobacco-pipes are also distinguished. Bohemian glass is noted all over the world; nor is the manufacture confined to Bohemia, for it extends to all the surrounding territories. Crown-glass and mirrors are the branches for which Germany is most noted. The beer of Germany was formerly celebrated throughout Europe, but has long been surpassed by that of Great Britain. Her cotton fabrics, as already observed, have nearly fallen to the ground, and her manufacture of silk was never considerable. The following may be enumerated as minor articles: — sugar-refinery, wax, oil, musical and mathematical instruments, clocks, watches, and woodwork toys. The German mechanics are usually formed into corporations, and are very skilful, holding the next rank to those of England. In cutlery they claim the pre-eminence.

2878. *Mining* is one of the sources of wealth in which Germany may be said to surpass every country in Europe. Nowhere has the science of mining been more studied, or brought to greater perfection. Metals and minerals are produced in remarkable variety: gold; silver, not very abundant, but superior to that of the other European countries, at least if Hungary be included; mercury and cobalt, also superior; iron, more abundant, and of better quality, than that of any other country, except Sweden; lead and tin, unrivalled, except in Great Britain; a profusion of salt and coal. The principal mining districts are Styria and Carinthia, Silesia, the Erzgebirge in Saxony, the Hartz in Hanover. The entire products of German mining have been thus estimated: — gold, 182 marks; silver, 123,000 marks; copper, 39,000 cwt.; lead, 191,200 cwt.; tin, 7980 cwt.; iron, 2,400,000 cwt.; mercury and cinnabar, 13,980 cwt.; cobalt, 16,500 cwt.; calamine, 82,800 cwt.; arsenic, 10,600 cwt.; bismuth, 1500 cwt.; antimony, 2,400 cwt.; manganese, 1800 cwt.; salt, 3,150,000 cwt.; coal, 20,000,000 cwt.

2879. *The commerce of Germany*, though extensive, is not equal to that which formerly existed, or to the advantages arising from her situation in the heart of Europe and of the civilised world. She was, after Italy, the first European country in which commerce revived; and the Hanseatic league once engrossed the whole trade of the north. In recent times, Germany has been outstripped by Holland, by Britain, and even by France. The German writers ascribe this decay to the want of unity consequent on the number of little states into which their country is split, which deprives its ships of a national flag, and of a powerful protection while navigating remote seas. Their shipping is chiefly confined to Hamburgh, Lubeck, and Bremen, the remnant of the Hanse towns, which still enjoy many of their old privileges in the ports of Europe, and whose flag is seen in every part of that continent. Germany labours under the difficulty of finding an outlet for the great quantity of commodities which she possesses fit for foreign markets; being hemmed in by nations more industrious than herself, destitute of colonies, and precluded by the maritime powers from any direct trade with the East and West Indies. These states rather look upon the great population of Germany as affording a market for their manufactures and the produce of their colonies. Her political disunion has been especially injurious to her internal trade, which would otherwise be immense. Each petty prince thinks only of promoting his own separate interest, by laying under contribution the commerce which passes through his territory. A boat which performs the whole navigation of the Rhine pays toll at twenty-seven stations: the number on the Weser is twenty-three; on the Elbe, thirty-two. The Danube and the Oder, the one passing chiefly through the territories of Austria, and the other through those of Prussia, are more free; but unfortunately the countries through which they flow do not afford the same scope for traffic. Treaties, however, have been for some time negotiating, by which it is expected that a great measure of freedom will be secured to the navigation of the German rivers.

2880. *The exports of Germany* include most of those productions in which she has been described as excelling: grain, salted provisions, especially hams; live cattle and hogs; timber; iron and steel; lead; salt; linen, linen yarn, and linen rags; some woollens to the north of Europe; porcelain, glass, ashes. In return for these essential articles, she receives nearly all the luxuries of life; the manufactures of Britain, the wines of France, the sweets and aromatics of the East and West; also dye-stuffs, and all the cotton and silk which are necessary for her own manufactures. From the disunited state of the country, no general account appears to be kept; but the German economists labour under a dread of the imports exceeding the exports, and the consequent supposed loss from an unfavourable balance.

2881. *The internal commerce of Germany*, notwithstanding all the obstructions under which it labours, is extensive. It owes this advantage chiefly to its noble rivers, on which vessels of large burden can pass nearly from one extremity to the other. The Danube, though the largest, and of longest course, is not the most beneficial. Its navigation is so difficult that vessels cannot make use of the sail, and must be dragged along by horses; rapids and cataracts obstruct it in several places; and its tributaries, the Inn and the Enns, descend only from the rugged heights of Styria and the Tyrol. It has a triple navigation, the ships of Ulm unlading their goods at Ratisbon, those of Ratisbon at Vienna, whence they are carried downwards through Hungary. The Rhine has a much more valuable navigation, continued from Switzerland to Holland and the Netherlands, and communicating by its great tributaries with the most fertile territories and the most industrious cities in the interior of Germany. It has of late been greatly facilitated by the employment of steam-vessels, which go up as far as Strasburg. The navigation of the Elbe is also very valuable. It begins at the junction of the river with the Moldau in the interior of Bohemia, and constantly improves, till at Hamburg the Elbe is capable of receiving the largest vessels. By means of the Spree and its canal, it communicates with the Oder, and brings down to Hamburg the productions of Silesia and Brandenburg. The commerce of the Oder itself flows chiefly in this channel. The Westphalian streams of the Weser and the Ems, though not of first-rate magnitude, are very commercial, giving support at their mouths to the ports of Bremen and Embden. The system of annual fairs for internal trade is still kept up in Germany to a much greater extent than in any other country. The grand fairs are those of Frankfort on the Mayn, for France and the Netherlands; Leipzig, for Russia, Poland, and the North; and also for the book trade; Bautzen, or Bolzano, for Italy. There are smaller fairs at Naumburg, Cassel, and Magdeburg; and a most extensive trade exists without fairs at Vienna, Augsburg, Nuremberg, Berlin, Cologne, and Breslau. Through these different channels is carried on an extensive interior trade, and a great foreign land-trade to Russia, Poland, Hungary, Italy, Switzerland, France, and the Netherlands.

2882. *Canals* have not been extensively introduced to improve the interior trade of Germany, though no country affords greater scope for them; as, by joining the Danube, the Rhine, and the Elbe, the most distant seas of Europe might be made to communicate. To such undertakings, indeed, the disunited state of the empire must be a great discouragement. A few only have been executed on a small scale, and chiefly in the north. Such are the Holstein canal, which joins the Eyder to the Baltic, and opens a communication between it and the North Sea; the Plaunsche canal, from the Havel to the Elbe, serving, with Frederick-William's canal from the Spree to the Oder, to connect the two great rivers of northern Germany, the Oder and the Elbe. The Vienna canal, completed to Neustadt, is intended to connect the Danube with the Adriatic.

SECT. VI. *Civil and Social State.*

2883. *The population of Germany*, according to official data collected in 1818 by the Diet, amounted to 30,375,679. The enumerations since made have generally exhibited a certain increase; and in 1830, a careful estimate, in the *Bulletin Universel*, from the works of Crome, Mohl, &c. rates it at 34,393,000. They inhabit 2433 cities, 2071 market towns, and 88,619 villages and farms, independently of single houses. Germany has no great capital, like France and England, in which the wealth, power, and civilisation of the state is as it were concentrated. On the other hand, no country in Europe has so many cities and towns of from 3000 to 5000 inhabitants.

2884. *The people who inhabit Germany* are distinguished into two races, the German and Sclavonian. The Germans are estimated at 24,700,000, and are divided into two families, High and Low German, distinguished less by physical differences, than by character, and particularly by the mode of pronouncing the language. The High Germans inhabit most of the territory south of the Hartz and its branches, Upper Saxony, Franconia, the Rhine, Swabia, Bavaria, all the Austrian dominions, and Silesia. The Low Germans are in Lower Saxony, Westphalia, Holstein, Mecklenburg, Brandenburg, and Pomerania. The Sclavonic races are reckoned at 5,040,000, and constitute the greater part of the population in Bohemia, Moravia, and Silesia. They are much inferior in civilisation to the Germans, but are a laborious race, formerly almost all in a state of bondage, but now mostly emancipated, and many of them possessing considerable wealth. Besides these leading races, there are about 175,000 Italians; from 20,000 to 25,000 French, and 250,000 Jews.

2885. *The social state in Germany* exhibits two very distinct portions, not running into, or blending with each other, as in most of the civilised modern states. The class of noble birth hold themselves as separated by the most marked and decided line from the body of the nation. They have divided themselves into high and low nobility. The high nobles are those who either possess sovereign sway, or are descended from those who did, and are called mediatised princes. The low, or feudatory nobles, are those who cannot boast that any sovereign power ever resided in their family. There is another distinction, that of the

old nobility, who must be able to count a line of sixteen noble ancestors, and of the young or short nobility. The cities, too, especially those that once ranked either as Hanse towns or as imperial cities, contain a class enjoying hereditary distinction as patricians or city nobles. The petty princes and great nobles of Germany thus retain much of the feudal habits, and their courts display rather rude baronial pride, and forms of empty pomp, than the polish and elegance of the great European courts. It must be owned, however, that they have produced many individuals of the greatest ability and most enlightened minds; and that their sway, though lofty, is generally mild, and even popular. The character of the body of the German people, has many estimable features. They are, perhaps, the hardest-working nation in Europe; slow, heavy, and laborious; and, through these qualities, have always been esteemed the most valuable colonists in newly settled districts. Their habits are simple and domestic; and plain honesty and fidelity usually mark their transactions. Rigidly excluded from court intercourse, their manners are somewhat plain and homely; and German wit, according to Madame de Staël, is the dullest of all possible things. Yet their poetry makes it evident that under this outward crust there is a vein of deep feeling and high fancy; partaking, indeed, too largely of mysticism; but we may add the universal taste for the highest class of music. The character of the Germans is very military; a quality derived from their feudal ancestors, and partly from their country having been the theatre of all the great wars which have been waged in Europe. "The common sounds," says Mr. Sherer, "in the cities of Germany are the clangor of military bands, the ringing of iron boot-heels, and the measured tread of stately soldiers:" hence the military character is said to rank higher there than in the neighbouring countries.

2886. *In regard to religion*, Germany has been the scene of the greatest revolution in modern times. In its bosom the Reformation sprung up; and within it were carried on the most formidable of the conflicts between the old and the new system. Elsewhere, one or the other finally prevailed; but in Germany they have settled into a pretty equal division of the country. Speaking generally, the whole south may be called catholic; the whole north, protestant. Of the greater states, the catholic religion rules in Austria and Bavaria; the protestant, in Prussia, Saxony, Hesse, and Hanover. A complete toleration is now every where granted to every profession. The Catholics still hold the majority, being reckoned at 18,000,000, the Protestants only at 12,000,000. Jews, Moravians, Mennonites, Hussites, and some smaller sects, make up the rest of the population.

2887. *In literature and science*, Germany has been particularly distinguished, and is perhaps the most learned and reading country in the world. Her writers exhibit that character of hard and somewhat mechanical labour, which distinguishes her workmen in other departments. They are voluminous, and eminent for profound research; while they want some of the lighter graces of composition. In editing and illustrating the classics, in biblical criticism, and in statistical researches, no nation can come into competition with them; and since, in abstract science, they can name Leibnitz, Kepler, and Euler; in medicine, Haller and Van Swieten; in mineralogy, Werner and Möhs, no nation can triumph over them in these pursuits. In the metaphysical world also they have recently made a great movement; and the names of Kant, Fichte, and Schelling, are ranked by their followers almost as demigods. We confess ourselves among those who are able to discover only faint glimpses of meaning in the works of these learned persons, and are inclined to think, with Madame de Staël, that "the empire of the air" has been the portion of German metaphysicians. That accurate thinking is not the function which works best in the national brain, seems proved by the recent general prevalence of animal magnetism; to which we dare not add the profound sciences of cranioscopy and craniology. Till within the last half century, Germany had no existence in regard to the belles-lettres, and the Teutonic language and genius were considered alien to every thing like fancy and poetry. Suddenly, however, Klopstock, Wieland, Schiller, Lessing, Göthe, claimed a place among the first poetical names, and distinguished themselves by bold and lofty flights of genius, which made a strong sensation throughout Europe. More recently the exploits of the war of liberation have been sung in very lofty strains by Körner. We must not even in this hasty sketch forget Humboldt, who has established his name as the most learned and eloquent of modern travellers.

2888. *The institutions for the promotion of learning* are very numerous in Germany. The chief learned societies are those of Munich, Berlin, Prague, and Göttingen; but, wanting the impulse of a national metropolis, none of them vie in celebrity with those of Paris and London. The universities are very numerous and very distinguished. Only five of them are catholic; that of Vienna is attended by 1103 students, Prague, 879; Weisburg, 331; Landshut, 640; Freyburg, 837. There are thirteen protestant universities, Heidelberg, with 603 students; Leipzig, 883, Rostock, 76; Griefswalde, 55; Marburg, 197; Jena, 522; Giessen, 241; Kiel, 107; Halle, 471; Göttingen, 1165; Erlangen, 143; Berlin, 1752. There are two of divided religion; Tübingen, which has 500 students, and Bonn, which has 400: in all, twenty universities, which in 1817 were attended by 10,481 students. Instruction is given, as in the Scottish universities, entirely by lectures; the students live in

the towns, and are not subjected to any academical discipline. They are in general diligent in their attendance at lectures, but somewhat disorderly in their private conduct. Duelling is practised in a systematic manner, and formed almost into a regular science; hard drinking is alleged to be prevalent; and an ardent, but somewhat irregular patriotism has led to the formation of secret political associations, which have become an object of jealousy to the German sovereigns. The lectures are public and private, of which the latter only are remunerated with fees, and are hence usually the most valuable.

2889. *There are also institutions called Lyceums*, which are numerous, especially in Austria, where lectures are delivered, but no degrees conferred. Common schools are also sufficiently numerous; and those for the instruction of the lower orders are so multiplied, that out of a thousand scarcely one will be found, it is said, who cannot read, or fifty who cannot write. In no country has education been more the object of study; and the systems of Basedow, Salzmann, Pestalozzi, and Jahn have attracted general attention.

2890. *The literary and scientific collections* of Germany are the most numerous and valuable that exist in any country. The imperial library at Vienna contains 300,000 printed volumes, 25,000 manuscripts, and about 70,000 pamphlets; that of Munich, 400,000 volumes; that of Göttingen, the most useful perhaps in the world, 280,000 volumes, 5000 manuscripts, and about 110,000 pamphlets; Dresden has 250,000 volumes; Wolfenbüttel has 190,000, including a rich store of ancient works, and 6000 bibles. Stutgard, 170,000 volumes, and 12,000 bibles. Berlin, 300,000 volumes in her public libraries; of which the king's contains 160,000. Weimar, Prague, Frankfort on the Mayn, Hamburg, Breslau, Mentz, Darmstadt, have each about 100,000. Marburg, Gotha, Jena, and many of the smaller cities, have very considerable libraries; and upon the whole it is calculated that in Germany four millions of volumes are accessible to the public. The cabinets of natural history, and especially of mineralogy, are numerous and valuable. The botanical garden of Schönbrunn, near Vienna, and that of Göttingen, are celebrated; as are the observatories of Vienna, Berlin, and Göttingen. The cabinet of medals at Vienna is the richest in Europe.

2891. *The book trade of Germany*, in unison with the general taste for reading, has reached an extent which equals, perhaps, that of all the rest of the world. The nation numbers about ten thousand authors, who not only produce original writings, but translate immediately every foreign work of any celebrity. The works thus produced are brought annually to the Easter fair at Leipzig, to be distributed among the booksellers of Germany. The new works annually produced amount to about 4000. The want of any literary metropolis where there could exist a permanent dépôt seems to have occasioned this arrangement, which appears in many respects cumbrous and inconvenient.

2892. *Of the fine arts*, painting was very early and successfully cultivated in Germany; though the works of Durer and Cranack have a rude and Gothic character, compared with those of the great Italian masters. In recent times, none of her painters have ranked in the first class, certainly that honour cannot be assigned to Mengs and Dietricy. Yet her princes have formed collections of paintings to which there is nothing equal out of Italy. The Dresden gallery holds the foremost rank; after which may be named the Belvidere at Vienna: the galleries of Munich, Berlin, Cassel, Augsburg, not to mention many private collections, especially at Vienna, which rival those of princes. To these are also attached very extensive collections of drawings and engravings. Music is the rage all over the nation; and the German composers, Handel, Haydn, Mozart, Beethoven, Weber, and Spohr, seem almost to have eclipsed the masters of Italy. In almost every village a concert of amateurs is to be found. Architectural genius has not shone with very great lustre. Very splendid edifices have been reared in the great capitals, and in the free cities during the days of their glory; but these have been chiefly formed upon Italian models. Sculpture has never risen above mediocrity. Engraving was early carried to great perfection by Albert Durer and others, called "the little masters," in a small and highly finished style; and in recent times, Frey, Wille, Schmidt, and Müller have maintained the reputation of Germany on a level with that of any other country.

2893. *Amusements, dress, food*. The amusements of the Germans are rather of a more gay and elegant description than their character would lead us to expect. We have already noticed the extreme ardour with which music is cultivated. Equally frequent is the kindred amusement of dancing. The *waltz*, the national German dance, has not obtained the approbation of the moralists of other countries, and indeed appears liable to serious objections; yet Mr. Sherer assures us that in its native land, and performed in its genuine style, it appeared to him sufficiently innocent. The dress of the Germans has now few distinctions from that which has become general over civilised Europe. The pomp of array among the Austrian and Hungarian nobles, and the blaze of jewels which they display, dazzle the other nations of Europe. In food, the Germans have some hard and harsh articles, which are national favourites; ham, sausage, raw herring, sauer kraut, acid wine; and these they contrive to prepare in a manner which renders them agreeable to the palates of the neighbouring nations.

SECT. VII. *Local Geography.*

2894. *The details of German geography* are of immense extent, and extremely intricate; from the vast number of sovereignties, great and small, into which the empire has been split; the manner in which those are intermingled with each other, and the numerous transferences of territory which have taken place. It must be confessed that some degree of simplification was effected by numerous *arrondissemens* made during the war of the French revolution, and the absorption of many of the minor powers into the domain of their greater neighbours.

2895. *The division into circles*, made by Wenceslaus in 1307, and by Maximilian in 1500, with reference to the different regions as parts of an elective empire, formed long the basis upon which every geographical description of Germany was founded. Its importance gradually declined, as Germany was broken up into entirely independent parts; and since the empire itself has been abolished, and the dignity of elector has ceased, the circles have no longer any political existence. Hence Hassel, in his recent description of Germany, has not even employed them as a principle of division, but has distributed the different parts solely according to the princes who actually hold sway over them. Yet the circles hold so great a place in history, and are still so frequently mentioned as recognised portions of Germany, that it may be advantageous to take a rapid sketch of their contents.

2896. (1.) *Austria*. (2.) *Bohemia*. (3.) *Bavaria*. The two first of these form the principal part of the hereditary dominions of the house of Austria; the last includes those of Bavaria, with little or no intermixture.

2897. (4.) *Swabia*. This circle is distinguished by its grand and bold aspect, produced by the Black Forest, the bordering mountains of Switzerland, and the upper course of the Rhine and the Danube. The dukes of Swabia, who for some time held the empire, have long been extinct. This circle comprises the kingdom of Wirtemberg, the Grand Duchy of Baden, and the great imperial cities of Augsburg and Ulm.

2898. (5.) *Franconia*. The dukes of Franconia, who once also ruled Germany, are nearly forgotten in that duchy. It has not been the seat of any considerable sovereign state, since the principalities of Anspach and Bayreuth were occupied by Prussia, who was obliged to cede them to Bavaria. This circle is chiefly distinguished by its great imperial cities, of which the principal are those of Nuremberg and Frankfort on the Mayn; the latter still retaining its nominal freedom, and its extensive home trade.

2899. (6.) *The circles of the Upper and Lower Rhine* comprise the most fertile and beautiful portion of Germany, the choicest vineyards of which are on its hills. Since the fall of the elector palatine, from whom a great part of it was called the Palatinate, it has been split into various parts, and occupied to a great extent by powers without the circle. Hesse-Cassel and Hesse-Darmstadt are considerable states, whose dominions lie chiefly within the Upper Rhine; while Prussia possesses the most valuable part of the Lower Rhine. This circle has been much distinguished by its sovereign bishops, those of Mentz, Trèves, Cologne, who ranked once as electors, and vied in pomp and power with the greatest princes. They gave way, however, before the late shocks, have been deprived of their sovereignties, and their domain reduced within very narrow limits. This circle is also remarkable for the chain of mighty fortresses, the barriers of Germany, which have been erected along the frontier stream of the Rhine.

2900. (7.) *Westphalia* is also a very miscellaneous circle, the chief portions of which belong to Prussia and Hanover. It does not appear to have formed an independent sovereignty, except during the ephemeral sway of Jerome Bonaparte. Westphalia is in general a level and fertile district, of which the inhabitants are industrious. It is traversed by the Weser and the Ems; and its foreign trade is carried on by the Hanse towns of Bremen, Verden, and Emden.

2901. (8.) *Lower Saxony*. The name of Saxony applies to that great extent of northern Germany originally occupied by the Saxons, the once powerful and warlike conquerors of Britain. It is generally level, forming a continuation of the immense plain of continental Europe. Lower Saxony consists chiefly of Hanover with Brunswick; but portions of it are held by the kings of Saxony and Prussia. The lower course of the Elbe flowing through this circle, makes it the theatre of an extensive trade, which centres chiefly in the great Hanse town of Hamburg.

2902. (9.) *Upper Saxony* is the most extensive, and perhaps most important, of all the circles. It includes Brandenburg, the central seat of the king of Prussia's territories, and Saxony Proper, which forms nearly the whole of the territories constituting the electorate, now kingdom, bearing that title. It contains the large and fine capitals of Dresden and Berlin. It has also a considerable extent of sea-coast; but this being on the Baltic, is not so favourably situated for commerce as that of Lower Saxony.

2903. *The local divisions of Germany* must now be considered according to the sovereigns by whom they are ruled; that being the only political distinction now recognised.

SUBJECT. I. *Austrian Dominions.*

2904. *More than half the dominions of the house of Austria are out of Germany. The Lombardo-Venetian kingdom, as a local division, came under Italy, and Galicia will come under Poland. Hungary, however, with its appendages, forms so extensive and important a territory as to be entitled to a separate chapter.*

2905. *The German territories belonging to the Austrian emperor consist of the archduchy of Austria, Bohemia, Moravia, Styria, Illyria, and Tyrol; the extent and population of which have been already given from the latest authorities.*

2906. *Lower Austria, or Austria below the Ems, forms as it were the metropolitan province, being situated in the very heart of this vast empire. It is composed of the deep and warm valley of the Danube, bordered on each side by considerably elevated mountain chains. Those on the south form a part of the great Alpine barrier; inferior, however, to the gigantic ranges of Switzerland and the Tyrol. They are called the Noric Alps: their higher eminences extend along the Styrian frontier, though they shoot long branches into the heart of Austria. The most elevated summits are the Schneeberg, 6521 feet; the Oelscher, 6060; the Wechselberg, 5574; the Simmering, 4416. On the northern side a chain of mountains, connected with those of Bohemia, separates the valley of the Danube from those of the Moldau and the Elbe; but it has no alpine character, and does not rival the elevation of the southern chain. Between the two lies another branch, of which the highest point is the Kalenberg, and eastward from which the land slopes down to the vast watery plains of Hungary. A great extent of these hills is covered with wood, while many parts on the contrary are rocky and barren; so that this is rather a picturesque than a naturally fruitful country. A large portion, however, is laboriously cultivated. The entire surface is reckoned at 2,870,000 jochs ($1\frac{1}{2}$ acres each), of which about 600,000 are water and waste, 1,280,000 arable, 78,000 vineyard, 650,000 pasturage, and 860,000 woodland.*

2907. *The produce of wine is reckoned by Blumenbach at 2,000,000 eimers (nearly ten gallons each); of which about 500,000 is exported, and 50,000 made into vinegar. The pastures, which are diminishing, sustained in 1815, 57,590 horses, 89,909 oxen, 196,565 cows, and 345,697 sheep. The breed of horses is greatly improved by the demand for the imperial studs, and that of sheep by the introduction of merinos. Lower Austria is the most manufacturing district of the whole monarchy. In 1819 it was reckoned to contain 18,044 looms, 520 printfields, and 2368 water-mills; giving employment to 57,121 manufacturers, independent of weavers, of spinners, and other workmen. These manufactures, in the order of their importance, are cotton, silk, linen, iron, copper, jewellery, glass. Vienna is also the centre of the internal commerce of the whole monarchy.*

2908. *Vienna (fig. 373.) the great and ancient capital of Germany, is seated on the*

VIENNA.

southern bank of the Danube, not more than twenty miles from the frontier of Hungary. The original city, surrounded by its once formidable walls, does not exceed a sixth of the space covered by the thirty-four suburbs, which stretch in an almost interminable extent, but are all surrounded by a brick wall serving for purposes of taxation and police. The body of

the place displays a sober and solid stateliness, without gloom. The houses are massive and lofty; and, like those of Edinburgh, divided among a number of families, with a common staircase. Every house has a master, who looks to its general cleanliness and security,

SQUARE OF IMPERIAL PALACE, VIENNA.

and shuts the common door at ten at night. There are on an average thirty-eight men in every house in Vienna, and there is one which contains 400. The city is rendered very handsome by the great number of mansions, justly entitled to the name of palaces, which are held by the high Austrian and Hungarian nobles. There are few very prominent single edifices. Even the original palace of the house of Hapsburg (*fig. 374.*)

is represented as a collection of dissimilar and ill-assorted masses, added to each other as convenience dictated. That of Belvidere is more attractive, from its rich collections ;

CATHEDRAL OF ST. STEPHEN.

of whom 142,654 were male, and 147,137 female. In 1810, 9,000,000 florins were paid for house-rent ; and the value of private houses was estimated at 150,000,000.

CATHEDRAL OF ST. LORENZO.

for those who have had the most extensive London experience. The driving a coach through with speed and safety is an attainment which the most skilful coachmen from other cities cannot attain without very long practice.

2909. *Vienna* is not a literary city, and is perhaps the largest that exists without an academy either of science or belles lettres. Yet there are few that contain more extensive collections of books, paintings, and objects of natural history, both in the royal palaces and the houses of the nobles. The censorship of the press is maintained with the utmost rigour ; and the great object of the court seems to be, that nothing shall appear which can in the smallest degree reflect upon the imperial house or government. Mr. Russell even reports of the present emperor, that, when treating of some seminary of education, he observed, " I do not want learned men ; I want men that will do what I bid them." The drama in *Vienna*, as over all Germany, is a favourite amusement ; but none of the leading dramatic writers belong to that city, which ranks, however, as the musical capital of Germany, and even of the world. If some of those whose names distinguish its harmonic annals were not native, at least they found there the patronage by which their exertions were excited, and their talents developed.

2910. *The manners* of the people of *Vienna* are the subject only of qualified encomium. They are described as a more eating, drinking, good-natured, ill-educated, laughing, and hospitable people, than any other of Germany, or perhaps of Europe. In regard to themselves, they are distinguished by a love of pleasure ; in regard to strangers, by great kindness and hospitality. The pleasures of the table seem to be prized in a very especial manner. The most profound skill is attributed to the cooks of *Vienna* ; and Dr. Townson even expresses apprehension that a scarcity of the livers of geese, their favourite dish,

and the rural palace of Schönbrunn, from its fine gardens. The cathedral of St. Stephen (*fig.* 375.) is the largest church in Germany, and unites all that is lofty, imposing, and sublime in Gothic architecture. A colossal and equestrian monument of Joseph II., by the German sculptor Zauner, adorns the square which bears that emperor's name. In other instances Austria has withheld this mark of gratitude from her great men : hence the relict of the great Marshal Laudohn, having placed a monument of him at his country seat, inscribed on it :— " Erected not by his country, not by his sovereign ; but by his widow." *Vienna* has a number of other churches that are highly ornamental, particularly that of St. Lorenzo (*fig.* 376.), a Gothic structure of great elegance. By the census of 1815, *Vienna* was found to contain 7150 houses, in which were 56,749 families, and 238,177 persons ; of whom 111,340 were male and 126,831 female. According to an official statement in 1829, the population had risen to 289,785 ;

In 1815, the year's consumption for the city was thus stated :— 84,000 oxen, 93,000 calves ; 70,000 sheep ; 356,000 eimers of Austrian wine, 40,000 Hungarian, only 600 foreign ; 571,000 eimers of beer ; 3,210,000 bushels of grain. *Vienna* is the most manufacturing city in the monarchy. In 1811 there were 10,800 looms, and about 60,000 people employed on them. The tradesmen of *Vienna* are also reckoned the best in Germany. There are 6000 masters, 23,000 journeymen, 6000 apprentices, and 24,000 females employed. Shoes of *Vienna* manufacture are in request all over Germany. The city is also very commercial ; and the bustle in its streets is not equalled even in an English trading town. The art of effecting a safe passage through them on foot, amid the crowd of carriages, hackney coaches, loaded waggons, and wheelbarrows, there being only a slight indication of foot-pavement, is said to remain a mystery even

might endanger the tranquillity of the empire. The citizens are seen in crowded parties of pleasure on the ramparts, and in the fine wooded public walk called the Prater, between the city and the Danube. This eager pursuit of pleasure is unfortunately not always confined within the bounds of innocence. The dancing balls, to which persons of every class are admitted, attract a large proportion, at least, of the most profligate. Mr. Russell has not hesitated to make a charge of general dissoluteness; and adds, that there is not a female in Vienna who will not increase her means of amusement and show by the sacrifice of her virtue. M. Sherer, however, "who scans his nature with a brother's eye," argues that the scum which floats on the surface must not be too partially taken as the criterion of the whole composition. The family parties in the Prater appeared to him to show rather an air of quiet and natural cheerfulness, than of dissolute gaiety; while the neatness and care with which the children were dressed, their smiling and happy countenances, seemed by no means to bespeak parental profligacy. They appeared to him altogether an honest, affectionate, cheerful, frank, and obliging race.

2911. *Lower Austria* has few other places of any consequence. Baden, fourteen miles to the south, on the frontier of Styria, and at the entrance of the beautiful vale of St. Helena, has become highly distinguished for the baths, from which it derives its name, and which attract from 2000 to 3000 annual visitants from Vienna. The springs, strongly impregnated with sulphur and carbonic acid gas, are considered specific in cutaneous diseases, and useful in many others. The bathers sit or walk for an hour or two up to the neck in water. Kloster Neuburg and Korn Neuburg, on the opposite banks of the Danube, are old castellated towns. Krems is also a well-built place, surrounded by old walls, and containing a lyceum and gymnasium. Aspern and Wagram are villages opposite to Vienna, only distinguished for the great battles fought there in 1809.

2912. *Upper Austria* is entirely a mountain region, an assemblage of lofty alps and glaciers, separated by valleys, and even by small plains, and presenting landscape, sometimes soft and pleasing, sometimes in the highest degree wild and romantic. These mountains consist of the main body of the Noric, and the borders of the Rætian Alps. Among the loftiest summits are the Gross Glockner, 11,982 feet high; the Viehhorn, 11,058; the Hockhorn, 10,854; the Dachstein, 9222; the Hohekreutzberg, 8688. On the opposite side of the Danube, Upper Austria is bounded, and in a great degree covered, by the Bohemian forest. It is most copiously watered, not only by the Danube, but by the Inn, the Traun, and the Ens; and has the Kammersee, the Mondsee, the Zellersee, the Traunsee, and other lakes, which are romantic and well supplied with fish, but of little extent. It is needless to say that the country is little fitted for agricultural purposes; yet there is no district of Germany which has been improved with greater diligence. Of 3,287,264 jochs, of which this rugged surface consists, not more than an eleventh part is abandoned to absolute waste. There are 837,000 arable acres, 1,167,000 pasture, and 969,000 wood. The quantity of grain produced is about 9,000,000 bushels. The chief branch of husbandry, however, is pasturage, and the meadows of Upper Austria are reckoned superior to any other in Germany. Horticulture flourishes, especially in apples, from which 40,000 or 50,000 eimers of cider are made. There are very extensive salt mines, yielding 900,000 cwt., and supplying a great part of Germany.

2913. *The cities in this rural district* are not of the first magnitude. Linz, the capital, and the seat of administration, situated on the Danube, is a well-built city; and its fine square, considerable castle, three monasteries, and bridge of 800 feet long over the Danube, give it a very handsome appearance. It has a considerable imperial manufactory of woollen. Wels, the capital of one of the circles, is smaller, but carries on some trade. Steyer, at the confluence of the Traun and the Steyer, is a very thriving place, the inhabitants of which have increased, since 1803, from 7000 to 10,000. It flourishes by its ironworks and by the manufacture of various articles; also by that of mixed woollen and linen cloths. Braunau, a small but very strong place, on the frontier stream of the Inn, has been considered the bulwark of the monarchy, though it did not, in any of the late wars, arrest the tide of invasion.

2914. *The bishopric of Salzburg* forms a detached district of Upper Austria, ceded for a time to Bavaria, but restored at the peace of 1814. It is a completely alpine region, presenting all the Swiss features of rocks, glaciers, torrents, and mountains covered with eternal snow. The Noric and Rætian Alps approximate, leaving between them the broad valley of the Salza, connected with many others, which present the most beautiful features of nature, and afford ample scope to human industry. Salzburg (*fig. 377.*)

377

SALTZBURG.

ranks with the most picturesque cities in Europe, being built on several irregular hills, with the loftiest alpine summits towering behind. Its edifices correspond altogether to the grandeur of the surrounding scenery. The strong castle, with the arsenal, the bishop's palace, and the cathedral, are built in the grandest style of architecture, and placed in the most lofty and commanding situations. Several other fine buildings were consumed by fire in 1818. Salt-

burg has a lyceum, with eleven professors; two libraries; containing together 56,000 volumes, and a school of medicine.

2915. *Steyrmark*, which we call Styria, is a considerable inland territory, immediately to the south of Lower Austria, once governed by its own dukes, but long since absorbed in the empire. It is divided into Upper and Lower Styria; the former of which, being the western part, is altogether alpine; while the eastern districts decline into lower mountains, then into gentle hills, and finally into almost a level plain, on the borders of Hungary. The mountains are not so elevated as those of Switzerland; and though some glaciers remain in the valleys throughout the summer, they do not regularly attain the limit of perpetual snow. The highest arc, the Grossenberg, 8381 feet; the Eisenhut, 7676; the Grimming, once accounted the loftiest, only 7540;

the Stauge Alpe, 7140. The Mur, which crosses Styria from west to east, and passes through Hungary into the Danube, is a broad and rapid stream; but its navigation is so obstructed, that it is only useful for floating down the timber made into rafts, which are often dashed to pieces. The Drave, the Save, the Raab, and the Ens water particular parts of Styria. Of the 3,800,000 jochs of which it consists, about 1,500,000 are woodland; 1,080,000 pasture; only 558,000 arable; 50,000 vineyard. The grain is chiefly maize (used both for the cattle and for the bread of the lower orders), rye and buck-wheat: and the annual produce is estimated, by Kindermann, at 7,800,000 bushels. Flax, hemp, and potatoes are general. The wine is reckoned at 1,000,000 eimers, and is stronger and more fiery than the Austrian. But the most valuable produce is that of the mines in the upper province, which are various; but the most considerable is very fine iron, peculiarly fit for being formed into steel. Besides the numerous furnaces employed in extracting the ore, there are large manufactures of scythes, sickles, and chopping-knives; a great part of the iron also is worked up in Austria, and is even exported to England and France. Of the eastern province, a considerable extent is occupied, not by German inhabitants, but by the Winden, a rude Slavonian race, who do not understand the language of the Germans, and live in a much poorer and ruder manner.

2916. *Of the towns of Styria*, Gratz, the ancient residence of the dukes, is the capital: it is situated on the Mur, in a fine valley, on the borders of the lower district. It is a handsome, bustling, and prosperous town, and contains many houses which may be called palaces. Indeed, it ranks the third in the hereditary dominions, and contained, in 1810, 2621 houses, with a population of 29,576. Its old walls and castle, situated on a high rock, no longer suffice to render it a fortified city. The church of St. Catherine, and the monument of Ferdinand II., are its chief ornaments. Its lyceum, the only one that exists in the province, has twenty-six professors, and a library of 70,000 volumes. It carries on a considerable trade, particularly in iron, and has two yearly fairs. The female population of Gratz are celebrated for their beauty. Bruck, the capital of a district in Upper Styria, is a small and dull town. Mosburg is a larger place, carrying on some trade. Cilly, Judenburg, capitals of particular districts, and Leoben, where the preliminaries of 1798 were signed, are only large villages. Mariazell, a village on the Austrian frontier, attracts crowds to view an uncouth image of the Virgin there deposited. It was once enriched by many precious donations, among which were the images, in silver, of the Empress Maria Theresa, and all her family; but her son, Joseph II., being pressed by financial difficulties, not only melted down his mother, and all his brothers and sisters, into coin, but seized a great part of the other treasures.

2917. *The kingdom of Illyria* was formed by Napoleon, after the peace of Presburg, when he had compelled Austria to cede to him the whole south-eastern angle of Germany, Carinthia, Carniola, and Friuli; to which he annexed part of Croatia, and the Tyrol. When all these territories returned under the dominion of Austria, she still retained the newly created kingdom, only severing from it the last two appendages. The kingdom, thus modified, contains a superficial extent of 13,590 square miles, according to Blumenbach, but only 13,480, according to Lichtenstein, who states the population at 1,065,000. Hassel, however, calculates it at 1,165,197; but Col. Traux gives 1,138,000 as the result of the latest enumeration in 1829. This region is extremely mountainous and rugged, though the highest chains are on the frontier of Upper Austria and Styria, where Illyria claims a part of the stupendous mass of the Gross Glockner. Its own proper chains are those of the Carniolan and Julian Alps, which cover the greater part of the territory, of which the loftiest pinnacles do not in general rise above 6500 feet. The large stream of the Drave passes through Carinthia, and that of the Save through Carniola, into Hungary. The rugged surface of Illyria is, in many places, very ill-fitted for corn, of which it, however, produces 9,000,000 bushels, chiefly of the coarser kinds, rye and oats. There is a good deal of flax, and a little hemp and silk. Cattle are fed in great numbers, and sheep in the more bare and rocky tracts round the Adriatic. Lead is produced more copiously than in any other part of the empire (about 2000 tons), and mercury more abundantly than in any part of Europe (640 tons); iron 17,500 tons, and considerable quantities of antimony, alum, vitriol, coal, and salt. The chief branch of manufacture is that of working in metals, iron poles, wire, scissors, sickles, hooks, &c. There is also a good deal of linen, and some woollen. The foreign commerce is considerable: the only sea-ports in the Austro-German territories, Trieste and Fiume, are situated in Illyria.

2918. *The physical structure of this country* is very singular, its mountains being composed of that soft and porous limestone which is subject to extensive perforation. Illyria is said to contain upwards of 1000 caverns, many of which receive and send forth subterraneous rivers. The most considerable is the Laybach, which issues at once a broad stream from the bosom of a mountain. Its caverned course is accessible by a majestic natural gateway, forty feet high, and regularly arched. This leads into a spacious cavern, beneath the gigantic walls and vaulted roof of which the river is seen flowing. The cavern cannot be traced far up; but the river is still heard rolling over its rocky bed in the interior of the earth. Of all the caverns, the most extensive is that of Adelsberg. The entrance is by two large apertures, into one of which a river flows, and accompanies the visiter in his progress through this dark passage. At length it reaches an extensive natural cavern, and having penetrated a ledge of rock, plunges under ground, and is seen no more. Here a precipitous rocky wall formerly arrested all further advance; but, about ten years ago, it was scaled, and found to lead to a double range of most magnificent caverns, or natural palaces, supported by pillars, and fretted with cornices of the purest stalactite. The columns are, in some places, so nicely clustered together, and so regularly arranged, as to resemble the nave of a Gothic cathedral. The roof is in part so lofty as not to be discoverable from beneath. Not a sound is heard beyond the occasional dropping of the water, except once a year, when a ball is given by the peasantry in one of the most spacious caverns. Here, many hundred feet beneath the surface of the earth, and a mile distant from the light of day, the simple music of the Carniolan rustics resounds through more magnifi-

cent halls than ever were built for monarchs. At the end of six miles, the range terminates in a deep, clear, and cold subterraneous lake, which has not yet been passed. The Lake of Zirknitz is another of the wonders of Illyria. Its celebrity is founded on the periodical flux and reflux of its waters into and out of the bowels of the mountain. In winter and spring its basin, measuring six miles by three, is entirely filled. On the approach of midsummer it begins to diminish, and in the course of a few weeks is entirely drained. A luxuriant crop of grass, or even rye, is then raised in its abandoned bed; and the sportsman shoots game, where shortly before he was fishing for pike. The caverns are then seen gaping, through which the waters descended; and at the end of autumn, when the rains set in, water rushes out from them and from others, and the lake is rapidly filled.

2919. *The cities of Illyria are*: — Laybach, an ancient place, the principal seat of government, containing about 10,000 inhabitants, a lyceum, and some manufactures of silk and porcelain. It is distinguished as having been the seat of that congress in which the Holy Alliance decided the fate of Italy. On a hill above it stands the strong castle of Subiana, the place of confinement for the Italian liberals. Clagenfurt, a town of equal size, has also a lyceum, some manufactures of cloth, and a considerable transit trade. Villach is only about half its extent, but has considerable traffic in the produce of the mines, and in the conveyance of goods between Germany and Italy. The only Austro-German sea-ports are in the kingdom of Illyria. Trieste, made a free port about the close of the last century, has increased so rapidly, as to be now one of the principal havens of Europe. Its population, in 1815, was 36,000, but has since risen to upwards of 42,000. In 1815 it was entered by 7676 large vessels, and 275,000 tons of goods were exported. Its exports to North America alone, in that year, amounted to 250,000*l.*, and the imports to 200,000*l.* Fiume, at the head of a more easterly bay, is to Hungary what Trieste is to Germany; but this trade not being so important, supports only a population of about 8000, and enables Fiume to send out from 1200 to 1500 sloops.

2920. *The Tyrol*, including Vorarlberg, is the most westerly of the German territories of the empire, and borders upon Bavaria and Switzerland. It is also the most lofty and rugged of all the alpine regions of Austria. It is, indeed, a sort of projection from Switzerland, which it entirely resembles, except in the absence of extensive lakes. It presents mountains reaching to the skies, and crowned with eternal snows, or with rocky pinnacles; awful abysses, with thundering waterfalls; fields of ice stretching miles in extent; avalanches rushing down the steep sides, — the whole aspect of nature presenting a scene of awful majesty and fearful beauty. The Oerteles, the highest peak yet measured, has been found to reach an altitude of 14,416 feet; and there are others, particularly in the Oestal, which might also stand by the side of Mont Blanc and Monte Rosa; but their height has not yet been ascertained. The Schernomand is 11,645 feet, the Phalleyhugel 9756, the Sollstein 9106. Some of the chief tributaries of the Danube (the Inn, the Lech, the Iser,) pour down from the heights of the Tyrol. Agricultural industry cannot flourish on such a surface; as, of 1,500,000 jochs, only a tenth can be subjected to the plough, and then only rye, wheat, and barley can be grown. The Tyrolese, however, have made all that was possible out of their rugged soil. They have a great store of horned cattle and sheep; valuable gardens, from which apples are sent even to Russia; good wine, though it will not keep; some tobacco; wood, and salt in abundance. The other mineral productions are in considerable variety, but of no great amount. The national character of the Tyrolese is excellent. They are honest, sincere, and open-hearted. Their attachment to their country, to its independence, and to the house of Austria, has been displayed in the most heroic manner. The exploits which their undisciplined and almost unarmed bands performed in the last war, form one of the brightest pages of modern history. They are almost all Catholics; but their religion, according to this creed, is genuine and sincere. Their enterprising industry is strikingly displayed by the boldness with which they mount the steepest cliffs, and are thence let down by ropes, in order to cultivate like a garden a little spot that to a stranger would appear inaccessible.

2921. *The towns of the Tyrol* are Innspruck, the capital; an ancient, well built, and considerable place, commanding the valley of the Inn, and the most direct passage from Germany into Italy. Halle, farther down on the same, flourishes by large mines of salt. Kuffstein is important as a military position. Trent, on the Adige, and near the borders of Italy, is a fine old city, celebrated for the ecclesiastical council held there in 1545—1562, which had so signal an influence on the political destinies of Europe. Roveredo, still further down, and almost Italian, carries on some silk manufactures. Botzen, or Bolsano, has a crowded market, where the German and Italian merchants exchange the commodities of their respective countries. Brixen, Bregenz, Feldkirch, (the last two in the Vorarlberg, and on the borders of Switzerland,) are also of some consequence.

2922. *Bohemia* is the most considerable and most valuable of all the Austrian territories in Germany. It consists of an extensive plain, completely enclosed by a ring of mountains, of which the Riesengebirge separate it from Silesia, the Erzgebirge from Saxony, those of the Bohemian forest from Austria and Franconia. These chains run from 3000 to 5000 feet, and none of them shoot up those awful pinnacles, covered with eternal snow, which range along the Swiss and Italian borders. Bohemia is the most completely inland country of Germany, being nearly equidistant from the North Sea and the Adriatic. With the former, however, it communicates by the great stream of the Elbe, which rises in and rolls through all Bohemia, receiving its great tributary, the Moldau, and all its other waters. There is, perhaps, no country on earth more amply stocked with all kinds of solid and useful commodities than Bohemia. Grain, cattle, timber, metals, are all in such plenty, that it is difficult to say which predominates. Of 7,769,000 jochs, 3,608,000 are arable,

which, in 1785, produced 52,000,000 quarters; the proportions of which were, 17,000,000 rye, 14,000,000 oats, 17,000,000 barley, 2,500,000 wheat; and the amount is now supposed to be from 50,000,000 to 60,000,000. Flax is raised to the amount of 8000 tons, which yet is not sufficient for the manufactures of the country. Horned cattle, though very numerous, have been somewhat diminished of late years; but the breed both of horses and sheep has been much improved. In 1817, there was a census, which returned 121,000 horses, 241,000 oxen, 601,000 cows, and 907,000 sheep. The hops are the best in the world, and there is a profusion of apples and pears; but the wines are in small quantity, and scarcely drinkable. From the mines are drawn various metals, of which the most peculiar is tin, to the amount of 275 tons. Even fishing is carried on very actively in this inland situation, by means of ponds, which are said to exceed 20,000 in number. The manufactures of Bohemia are also most extensive. That of linen is the staple, including not only the common fabrics, but the finer ones of damask, cambric, lawn, and tape. In 1811, this manufacture was said to employ 400,000 spinners, 55,000 weavers, and 3000 bleachers. That of wool once employed 50,000 spinners, and 20,000 weavers and other workmen. In the cotton branch, the number employed is computed at 36,000. There are 3000 hat-makers; and the glass of Bohemia is famed over all Europe. In 1801, the entire value of Bohemian manufactures was reckoned at nearly 4,000,000*l.* sterling; the pay of the workmen 1,500,000*l.*, and that of the spinners 400,000*l.* Yet it is remarked, that there is little appearance of the wealth which Bohemia actually contains. The nobles, indeed, possess immense estates, the value of which is estimated at nearly 45,000,000*l.* sterling, firmly secured by entails and other legal provisions; but they spend their fortunes chiefly in profuse pomp and luxury at Vienna. The population, in 1775, was only 2,531,000. In 1817 it had increased to 3,236,000; but by the census in 1827, to 3,783,630: of these 1,810,742 were males, and 1,972,898 females. Two thirds are of Slavonic race, and there are about 50,000 Jews. The Bohemians, beyond any other German people, made an early and noble stand in the cause of civil and religious liberty. Not only after Luther, but long before, the standard of the Reformation was reared, after the death of John Huss and Jerome of Prague; but these glorious efforts had a fatal issue. Overwhelmed by the arms of Austria, the Protestants were either driven out of the kingdom, or compelled to renounce their worship; and it was not until the end of last century, when the principles of toleration began to influence even the Austrian cabinet, that about 34,000 Protestants resumed the exercise of their religion. Amid the same convulsions, the civil rights for which Bohemia had so nobly contended were all wrested from her, and she retains only a semblance of national states.

2923. *Prague* (*fig. 378.*), the capital, is situated in the very centre of the great plain of

378

PRAGUE.

Bohemia. Its bridge, its old Gothic cathedral on a hill, the vast and decaying palaces of the ancient nobles, the old style of architecture in the private mansions, unite to give it an antique and characteristic grandeur. In the cathedral is particularly distinguished the magnificent silver shrine, which has survived the wars of centuries. Among the vast forsaken palaces may be distinguished that of Wallenstein, the frescoes of which are still bright; and that of Czernim, still more vast, but quite dilapidated. Prague appeared, on

the whole, to Mr. Sherer, more picturesque and more impressive than Vienna. The population, in 1817, amounted to 79,606, of which 6783 were Jews; but, by documents collected in 1826, Dr. Sulzig estimates it at 105,000 independent of 12,000 troops in garrison. Of these, 527 were clergy, 883 nobility, 2093 public functionaries, and 5608 artisans. There is a considerable spirit of literature, and of making literary collections in Prague. It has an academy of sciences, an university with 44 professors and 879 students, and a library of 100,000 volumes. There is a national museum, an academy of painting, fifteen good picture-galleries, and a conservatory of music. The trade of the kingdom centres very much in Prague; and three great annual fairs are held there. The city is kept very clean, but indifferently lighted, and some of its streets are unpaved.

2924. *Bohemia* has a number of little towns of from 2000 to 5000 inhabitants, but no great cities, except its capital. We may mention Budweis, Pilsen; Königsgratz, a strong place on the Silesian frontier; Eger, a military position on the side of Franconia; Tabor, founded by the Hussites, who gave it this scriptural name; Töplitz, celebrated for its baths. The manufactures are chiefly carried on in small towns and villages, and do not accumulate in the larger cities.

2925. *Moravia*, in which we shall include the small part of Silesia which remains to Austria, is a country of less extent than Bohemia, but of nearly similar aspect, and equally fertile. It has also a frontier of high mountains; being bounded on the one side by those which separate it from Bohemia, on the other by the

Carpathian mountains, beyond which are Poland and Hungary. Smaller chains penetrate the country, and render the full half of it mountainous; but broad and fruitful valleys intervene, and the southern part consists of fine and extensive plains, the soil of which is peculiarly rich. The March or Morava, rising in the Silesian frontier, traverses the whole country, bearing all its tributary waters down to the Danube. Moravia contains 2,070,000 jochs arable, 750,000 pasture, 50,000 vineyards, 1,120,000 in timber. The produce is, wheat, about 2,600,000 bushels; rye, 8,000,000; barley, 3,500,000; oats, 16,000,000. The live stock, 127,000 horses, 357,000 oxen, and 402,000 cows. The produce of flax is also very great. This is a distinguished manufacturing province. The woollen branch flourishes more than in any other part of the empire; employing 10,000 looms, and 100,000 men, not only in common cloths and flannels, but in kerseymeres and other fine fabrics. The general staple of linen is not less flourishing; employing 26,000 looms, 15,000 weavers, and 200,000 spinners. Cotton also gives employment to 10,000 people; and the hosiery amounts to 200,000 woollens, and 140,000 cotton stockings. Moravia and Austrian Silesia, in 1817, contained 1,733,000 inhabitants; of whom 450,000 were of German, and 1,250,000 of Slavonic race, with 28,000 Jews. By the census of 1825 they had increased to 1,968,000.

2926. *The towns of Moravia are considerable.* Brunn and Olmutz are both strong fortresses, and barriers of the empire. The former, containing 27,000 inhabitants, is the seat of government, and has extensive manufactures of fine woollens. Olmutz is a great market for Russian and Hungarian cattle. Iglau, an open town, has considerable manufactures, and is the greatest thoroughfare in Moravia. Znaim, the ancient seat of the Moravian princes, is now chiefly supported by its great military hospital. Troppau and Jägerndorf, in Austrian Silesia, are strong and pretty considerable towns.

SUBJECT. 2. *Prussian Dominions.*

2927. *The German dominions of Prussia* are extensive and scattered, variously acquired by successive inheritance and conquest. They consist of Brandenburg, the original basis of the monarchy; of Pomerania and Silesia; and of territories in Saxony, in Westphalia, and on the Rhine.

2928. *Brandenburg* forms a great mass of territory in the eastern part of the north of Germany, bordering on Poland. It is usually called the Mark of Brandenburg, and comprises the cities of Berlin, Frankfort, and Potsdam; containing 15,480 square miles, and 1,926,995 inhabitants in 1827: it is neither the most fertile nor the most beautiful part of this great country. It consists of a vast plain of sand, in some places presenting a dead level, in others blown into hills of little elevation. The grain, though carefully cultivated, is not sufficient for internal supply, but is of excellent quality. Tobacco and flax are cultivated with success. The breed of horses and oxen has been improved; but the pastures are not sufficiently rich for them. Sheep are bred in great numbers on the sand-hills; and their wool, improved by the mixture of the merino, ranks next to that of Silesia. The woods cover a fourth part of the surface, but are chiefly firs and pines, affording excellent masts, with some good oak forests. The manufactures, few of which originally belonged to the district, having been patronised with great zeal by the government, have considerably increased. That of woollens is the most extensive; the next in importance are linens and silk: porcelain and other ornamental fabrics are carried on at Berlin. The inland trade is very considerable, being favoured by the great rivers which pass through the province. The Elbe, indeed, only touches its western border; but its great tributaries, the Elster and the Spree, cross all Brandenburg; and the Oder runs through it from the north. The navigation of these rivers is greatly aided by the canals that unite them.

2929. *Berlin, the capital of Brandenburg*, and of the Prussian monarchy, is one of the finest cities in Europe; being the recent and studied creation of an absolute monarch, it has been formed upon a regular plan, and on a liberal scale of expenditure. The Brandenburg

BRANDENBURG GATE.

380

Gate (*fig. 380.*) is considered the most simple and majestic portal in Europe. On the entablature stands a bronze figure of Victory, one of the trophies carried off by the French, but which Prussian victories have now restored to its place. This matchless gate forms the entrance into the Linden-strasse, which, as a street, is perhaps also without a rival. It is divided, by double rows of linden or lime trees, into fine alleys, which afford delightful walks, and along which are ranged edifices of

the most majestic and classical character. Among these are chiefly remarked, the palace situated on the Place de Gendarmes (*fig. 381.*), seen along a line of lofty façade, ornamented with porticoes, statues, and every variety of sculptural decoration; the Italian opera-house, the churches, and the theatre, built with the intention of eclipsing all the other productions of Prussian architectural taste. Mr. Russell, however, complains that there is something monotonous in the design, which is uniformly that of an Ionic portico on a very simple front. The same fault he imputes to the other streets and squares, though they are broad, spacious, and regular. The Spree, which divides Berlin, has only the appearance of a broad ditch, navigated by flat-bottomed boats. On the opposite side is the old town, a

scene of traffic, with little pretension to beauty. The population, which in 1726 was only 94,419, had risen in 1827 to 223,520. Out of every hundred, fifteen were military. Berlin is a busy city, carrying on various manufactures of woollen, linen, and particularly silk,

PLACE DE GENDARMES, BERLIN.

academies of science and the fine arts; a splendid public library; cabinets of natural history; a botanic garden containing 12,000 exotic plants; a picture gallery, not so rich, however, as that of Potsdam, the pictures in which, by the last accounts, were to be added to this collection.

2930. *The other towns of Brandenburg* are not of first-rate importance. Potsdam, designed by Frederick the Great as a military residence, is regularly and very handsomely built; yet, according to a late writer, it suggests no other idea than that of a barrack. On every side are seen stiff figures of recruits moving slowly to the marching step, under smart and severe instructors. Frederick's palace of Sans Souci is remarkable for the extreme simplicity of those apartments which were occupied by himself: it contains one of the finest picture-galleries in Germany. Frankfort on the Oder cannot challenge a comparison with its namesake on the Mayn: it is still a considerable town of 15,500 inhabitants, with a strong bridge over the Oder, which is here a broad and spacious stream. It has some manufactures, and a considerable trade, holding five yearly markets, much frequented by the Russians and Poles. Brandenburg, the old capital, is still a city of 12,000 inhabitants. Kustrin and Spandau are little fortified towns, the former of great strength.

2931. *Pomerania* is a long line of narrow, sandy coast, lying along the Baltic. The Oder here enters that sea, forming at its mouth a large and winding *haff*, or bay, on the opposite side of which are the large islands of Usedom and Wollin. It is divided into the governments of Stettin, Stralsund, and Koslin, containing a population of 869,958. The soil is in many parts far from productive; yet in others, especially that which formerly belonged to Sweden, it is made by industry to yield harvests of grain more than sufficient for the interior supply. There are few manufactures; but the commodities of Brandenburg and Silesia are brought down the Oder, and exported from Stettin, Stralsund, and other ports. Stettin, the capital, is not only one of the strongest fortresses, but one of the most flourishing commercial cities in the monarchy, containing a population of 25,000, including the military. About 1200 vessels annually enter and quit its port. Stralsund, the former capital of Swedish Pomerania, lies in a wide flat territory, separated by a narrow channel from the great island of Rugen, and so enclosed by bays and lakes that it can communicate with the continent only by bridges. It ranked as one of the most celebrated fortresses in Europe, and bade defiance to the utmost efforts of Wallenstein; but the walls are now suffered to go to ruin, and the ramparts are used only as a promenade. The vessels which entered and quitted its port in 1827 were 6324. Anklam, Stolpe, Wollin, Stargard, and Koslin, are also ports and towns deserving of mention.

2932. *Silesia* is an extensive oblong tract between Bohemia and Poland. It was originally a Polish province; but German settlers have now occupied the greater part of it, and introduced industry and prosperity. From its fertility, and the industry of its inhabitants, it is considered the brightest jewel in the Prussian crown. The first exploit of Frederick the Great was to seize possession of Silesia: the main object of all the wars waged against him by Maria Theresa was to recover this territory; the final annexation of which to Prussia raised her to the rank of one of the great powers. The Oder, rising on its southern border, divides it into two nearly equal parts, of which the western is mountainous or hilly: its population is altogether German, and it is the seat of the principal manufactures; while the eastern consists, in a great measure, of flat and sandy plains, and is partly occupied by Slavonic races. The principal mountains are the Riesengebirge and the Sudetes, on the borders of Bohemia and Moravia. Of the Riesengebirge, the most elevated summit is the Schneekopfe, 5000 feet high; and though not adorned by lakes, it exhibits very picturesque scenery, which has gained it the appellation of "German Switzerland." Silesia contains 15,600 square miles, and is divided into the governments of Breslau, Oppeln, and Lignitz, which, in 1827, comprised a population of 2,362,562 persons: the number of inhabitants in 1817 was 1,992,598. Of 12,400,000 acres, excluding tracts altogether naked and moun

tainous, 6,900,000 are under the plough; yet, so great is the population, that it is only in favourable years that the produce of grain suffices for the consumption of the people. Flax is cultivated in a very great quantity; yet still not sufficient for the immense manufacture of which it is the material. Hops, tobacco, and madder are also considerable productions. The live stock that is reared is not adequate to the wants of the country, with the exception of sheep, which, even in 1802, amounted to 2,229,000; and their wool has been brought to such perfection as to be an extensive object of export, in a great measure superseding the Spanish in the market of Britain. Silesia is, perhaps, the most manufacturing country in all Germany; its linens, in particular, are considered the best in the world for pliancy, brilliant whiteness, and durability. In 1805, they employed 35,000 looms, producing in value about 12,000,000 rix-dollars; but Bonaparte's decrees, and the successful rivalry of Ireland and Scotland, have greatly lowered the amount, which is now only estimated at from 7,000,000 to 9,000,000, of which from 5,000,000 to 7,000,000 are exported. About half of the inhabitants are employed in spinning. Yarn is exported; and a great quantity of Bohemian cloth is brought hither to be bleached. The seat of the manufacture is chiefly in the mountainous district, where the numerous streams and the purity of the water are highly favourable to its various processes. The woollen fabric, though less considerable, employs 5500 looms, and is reckoned to produce 5,000,000 rix-dollars. The mineral kingdom is very productive, the returns being 10,000 tons of iron, 2677 marks of silver, besides copper, lead, arsenic, &c. The trade of Silesia consists in the exportation of its manufactures, chiefly by the ports of Hamburgh and Stettin, and in the importation of grain and cattle from Poland and Moldavia; of wine from Austria, and of India goods, silk, and cotton, by way of Hamburgh.

2933. *The towns of Silesia* are close-built, well fortified, not very large, but in a thriving state. Breslau, the capital, however, in 1827, contained 87,119 people, besides the military, and is the centre of the whole trade of the province, maintaining intimate communications with Hamburgh, Stettin, and Dantzic. It has also a flourishing university, an extensive library, and other valuable collections, and has given birth to many learned men, particularly Garve and Wolf. Schweidnitz was considered of immense strength, and was made by Frederick his chief place of arms during the seven years' war; but when Napoleon obtained possession of it in 1807, he demolished the fortifications, which have never been restored. Glatz, in a beautiful mountain valley, has two castles, both reckoned masterpieces of modern fortification. Lignitz is less remarkable for its own strength than for the signal victory there gained by Frederick over the Austrian army in 1760. Hirschberg, situated amid the most romantic scenes of mountain Silesia, is crowded in summer with admiring visitants. The other fortress towns of importance are Gross Glogau, on the Oder, and Neisse, on the river of that name, in a marshy country, surrounded by a spacious wet ditch. Brieg and Görlitz are considerable open towns.

2934. *Prussian Saxony* forms a large extent of straggling territory, consisting of portions severed at various times and in various ways from all the neighbouring states, great and small, sometimes having fragments enclosed within them, and sometimes enclosing within itself fragments of them. Generally speaking, it may be viewed as nearly a square territory, extending on both sides of the Elbe, between Royal Saxony, Brandenburg, and Hanover. It is divided into the governments of Magdeburg, Merseburg, and Erfurt, containing 1,396,240 inhabitants. It belongs generally to the vast, wide, flat plain of northern Germany, though on its western side it borders on the Hartz and the forest of Thuringia. There are considerable sandy and marshy tracts, but upon the whole it is abundantly productive of grain, which is cultivated with particular skill and diligence. Flax and tobacco, with rape and linseed, are also in great plenty. Horses, and horned cattle are kept up merely for the purposes of cultivation, but sheep are in number about 1,000,000, and the Saxon wool ranks with the very best in Europe. The mineral wealth is considerable, especially salt, of which a great vein traverses nearly the whole of this territory. The common manufactures of linen and woollen are generally diffused, without being carried to any remarkable extent. The Elbe, which divides the province into two parts, affords the opportunity of a very active trade. The territory is rated at 10076 square miles, and its population in 1817 amounted to 1,396,219. The inhabitants are almost entirely German and Protestants, this having been at an early period the grand seat of Luther's reformation.

2935. *The towns are not generally very large*, but numerous, ancient, well fortified, and celebrated in the history of German warfare. Magdeburg, which may rank as the capital, has always been considered one of the strongest places in Europe; and, for its noble defence against Charles V. and Tilly, was regarded as the bulwark of the protestant cause. Its works are of immense extent, bounded on most of its circuit by the Elbe, and in the rest by a ditch, not wet, but very broad, and carefully undermined. The horrible sacking of Magdeburg by the imperialists, in 1631, is still vividly remembered there, with execrations on the memory of Count Tilly, by whom it was sanctioned. It is a fine old city; the houses large and massive: it has a spacious market-place, adorned with the statue of Otho the Great, and an irregular but very broad principal street. Once a powerful free city, it now contains 32,000 inhabitants, a number of manufactures, and enjoys a considerable trade up and down the Elbe. Erfurt, formerly one of the principal cities, and a central mart, in the north of Germany, has now completely yielded the palm to Leipzig; and, instead of 60,000, contains only about 18,000 inhabitants. It is still a strong fortress, forming the key between Saxony and Franconia. Wittenberg, formerly a distinguished Saxon capital, where the standard of the Reformation was first reared, is now only a small but strong town. Halle is a large city of 21,500 inhabitants, with one of the most flourishing and crowded universities of Germany, and enriched by extensive saltworks in its neighbourhood. Halbertstadt is also a large open old town, of 15,000 inhabitants. Quedlinburg was once distinguished for the unbounded wealth of its nunnery, the abbess of which had the principal seat and vote on the bench of prelates; but since 1696 its wealth and privileges have been vastly curtailed. Mühlhausen, Merseburg, Weissenfels, Naumburg, Torgau, Stendahl, Salzwedel, are also considerable towns, of from 4000 to 8000 inhabitants. Lutzen is only a village; but its site is distinguished by the victory and fall of Gustavus Adolphus, the great protestant hero.

2936. *Prussian Westphalia* is also an aggregate of a number of small detached parts; but by cessions and arrondissemens it has been formed into a pretty compact territory, situated between Hanover and Holland, and extending from the Weser nearly to the Rhine. It extends to 8272 square miles, and its three governments of Munster, Minden, and Arensburg contained, in 1827, a population of 1,207,712. The Lippe divides it into two parts; the northern belongs to the great plain, which is sandy and marshy, but affords some good corn-land; the southern is covered with ranges of little rocky hills branching from the Hartz which render the soil often unfit for the plough, but it is always covered with fine wood. The staple to which Westphalia owes its celebrity consists in its hogs, which surpass those of all the other provinces, producing the hams so much famed throughout Europe. The valuable minerals of iron, coal, and salt are also very abundant. There are extensive manufactures of coarse linen, and a few which produce that of finer quality. Upwards of 20,000 looms were at work in 1816. The trade of the province consists in sending these productions down the rivers to Bremen and Holland; but Prussian Westphalia at no point reaches the sea, or even extends to the Rhine.

2937. *The chief towns of Prussian Westphalia* are the capitals of its three districts, Munster, Minden, and

Arensberg. Munster, once the seat of a sovereign bishop, and too well known from the excesses committed by the Anabaptists during their temporary possession of it, is still a flourishing place, which between 1802 and 1817 increased its population from 12,797 to 18,218. The peace of Munster, in 1648, forms one of the great eras of European history. Minden, celebrated for the signal victory achieved by the British arms in 1759, lies on the Weser, and carries on a considerable trade. A beautiful landscape is here formed by the river, its numerous little tributaries, and a range of wooded mountains, between which the Weser opens the passage called *Porta Westphalica*. Arensberg, once the seat of a count of that name, and Paderborn, the see of a bishop, were distinguished places in the middle ages, but have greatly declined. Bielefeld is the centre of Westphalian manufacture, especially that of damask, and of other kinds of fine linen. In 1811 there were exposed in its market upwards of 2,000,000 ells. In the surrounding meadows seventeen bleachfields employ 450 labourers. There is also a surprising number of little towns, of from 2000 to 5000 people: Rucklinghausen, Kosfeld, Steinfurt, Herforden, Brakel, Wasburg, Lippstadt, Sost, Hamm, Dortmund, Hagen, Iserlon, Altona, and Siegen.

2938. *The Rhenish provinces of Prussia* consist of two parts; one bearing the compound appellation of *Julich-Cleve-Berg*, and the other that of the *Lower Rhine*. The population of the whole amounts to 2,168,163.

2939. *Julich-Cleve-Berg* consists of the three grand duchies of those names, incorporated with the city and part of the bishopric of Cologne, the Prussian part of Guelderland, the abbeys of Essen and Werden, and a few other small places. It occupies almost ninety miles of the course of the Rhine, extending on both sides of that river. Of all the Prussian territories it is the least favoured by nature. On the eastern bank extends a continuous range of mountains, including the remarkable group called the *Siebengebirge*, or *Seven Hills*; not, indeed, exceeding the height of 2000 feet, but naked and rugged. The opposite bank is, indeed, level, but consists almost entirely of sandy plains and wide morasses: the country, therefore, does not produce corn sufficient for its own consumption, nor any thing in abundance except flax. Under these natural disadvantages, however, the inhabitants exert a manufacturing industry beyond what is found in any other part of Prussia, or even of Germany. The grand duchy of Berg has been called *England in miniature*, such is the variety of fabrics carried on there. Cloth, metals, and tobacco are worked up in almost every shape, and are exported to the value of 3,000,000 rix-dollars. The consequence is, that this district, so little favoured by nature, is the most populous, in relation to its extent, of any that belongs to Prussia. The area is only 3476 square miles; while the inhabitants, according to Hoffman's table, amounted, in 1817, to 935,040. It carries on a considerable trade along the Rhine and its navigable tributaries, the Ruhr and the Lippe; the Meuse also runs along its western border. The hills, particularly the *Siebengebirge*, present many peculiarly bold and picturesque sites, as they rear their heads above the river, crowned with ancient castles.

2940. *Some fine cities adorn the territory.* Cologne (*fig. 382.*) is one of the most ancient in Germany, and till 1797, was an imperial city, and the seat of a bishop, who was once an elector. It still contains above 50,000

COLOGNE.

of the prettiest cities in Germany, though its walls serve only for a promenade, and its splendid collection of pictures has been conveyed to Munich. Its spacious squares, its handsome houses, arranged in regular

DUSSELDORF.

streets, and the fine gardens which surround the city, constitute its attractions. It has also a good deal of trade; and though the population between the years 1787 and 1804 had fallen from 12,102 to 11,844, it has again risen as high as 18,000. Clèves, a much smaller town, is situated two miles from the Rhine, with which it communicates by a canal. The late palace of the grand duke is still surrounded by extensive gardens, which are open to the public. Bonn, a well-built imperial city, of 10,000 inhabitants, has a strong castle, now in a great measure neglected. Elber-

feld and Krefeld are large and flourishing places; its chief seats of manufacture, Rees, Solingen, Muhlheim, Reuss, Lennep, are also deserving of mention.

2941. *The province of the Lower Rhine* occupies a considerably greater extent of the course of the river higher up, than that last described. The principal part of it belonged formerly to the archbishopric of Trèves, which, with various little states and cities, has now merged into the Prussian dominion. The Rhine flows through the middle of this tract, receiving on one side the Moselle, and on the other the Lahn and the Lieg. The province is almost wholly mountainous, the principal chains in the west being the *Hundsruck*, a rocky calcareous group, widely extended, but not more than 1500 feet high, and from whose sides vast woods overhang the Moselle. The tract of *Ardennes* also touches the extreme frontier; and on the east, the principal chains belong to the *Wasgau*. The banks of the rivers are generally planted with vines, and present the most beautiful and pleasing sites that are to be found in any part of Germany. The soil and climate are very various; but though many tracts are doomed to inevitable sterility, a very great part is under careful cultivation. Rye and oats are the chief grains; but the most characteristic objects are the wines of the Rhine, particularly those of *Hockheim* (denominated *Old Hock*), and those of the *Moselle* and *Ahr*: they are celebrated over

Europe, and from 26,000 to 28,000 acres are occupied in producing them. As a manufacturing district, the present by no means rivals that above described; yet there is in Aachen a very extensive fabric of cloths, some of which are exported. These cloths, with wine and wood, form the basis of a considerable trade, independent of the passage of vessels up and down the Rhine. The area is 6332 miles; the population in 1817 was 972,724.

2942. *Coblentz*, at the junction of the Rhine and the Moselle, is the capital of the Prussian province of Lower Rhine, situated at the confluence of the Rhine and Moselle. It is a very ancient city, once the frequent residence of the emperors of the Carolingian dynasty, and afterwards of the princes of Trèves. It contains, therefore, many fine old edifices, both public and private. During the French revolution it was for some time the residence of the exiled court, and the asylum of the emigrant nobility. The situation is delightful, and it is a considerable depôt for the Rhenish and Moselle wines brought down for embarkation. On the opposite side of the river is Ehrenbreitstein (*fig. 384.*), a small town, on a rock above which stood one of the strongest fortresses in Europe: it was demolished in 1801.

384

EHRENBREITSTEIN.

2943. *Of the other towns*, Trèves is considered one of the most ancient either in France or Germany, being noticed by the Romans under the appellation Trevirorum Civitas. The inhabitants have even a boastful proverb that "before Rome was, Treveri stood." It was a great city in the middle ages, and contains many superb churches and convents as monuments of its former grandeur; but many of them are now empty, and going to ruin. The place has still 12,750 inhabitants, and a considerable trade with France, and in the wine and wood of the Moselle. Aachen, better known as Aix la Chapelle, is the largest town of the territory, containing a population of 32,000 chiefly employed in manufactures. These consist chiefly in kerseymere and other fine woollens, which occupy 1358 looms, and produce a value of 400,000*l.* The city is also very ancient, having been a residence of the emperors, and the place of their coronation. Being built, however, on an irregular spot of ground, its streets are extremely uneven, narrow, and dirty. Kreuzenach and Saarbruck are also considerable towns, and Saar-Louis is a strong fortress. St. Goar and Bacharach are only villages; but a great quantity of the finest Rhenish wine is brought down to them. *Neufchâtel* has been noticed under the head of Switzerland.

• SUBJECT. 3. *Smaller States.*

2944. *Bavaria*, next to Austria and Prussia, is the most powerful of all the German states. At various periods, the princes of Bavaria have been seated on the imperial throne, and their house even attempted a rivalry with that of Austria; but the disasters of the war of the succession, during which Bavaria followed the adverse fortunes of France, sunk it into a rank decidedly secondary. It obtained, however, a great increase in 1777, on the accession of Charles-Theodore, who brought into it a great part of the upper palatinate of the Rhine. In the beginning of the present century, it obtained a much more remarkable enlargement from Napoleon; who hoped to attach his vassals by aggrandising them, and was finally the dupe of that policy. The elector of Bavaria received from Austria the Tyrol, Salzburg, and part of Upper Austria; from Prussia, Anspach and Bayreuth. At the downfall of Napoleon, Bavaria was obliged to restore all that had been taken from Austria; but she was indemnified by the territory of the free imperial cities, Augsburg, Nuremberg, Wurtzburg, and others, once great and powerful, whose burghers were princes, and whose almost impregnable walls enabled them to defy the greatest monarchs, but who had sunk under the recent political shocks. These acquisitions, joined to the entire circle of Bavaria, gave to that power a territory of 32,834 square miles, according to Hassel; but Rudhart, in his comprehensive statistical tables, in 1824, allows only 30,404. The new acquisitions in Swabia and Franconia form a tolerably connected state with Bavaria; but the Rhenish territory is a portion entirely severed from the rest of the monarchy. Bavaria has a mountainous character, produced chiefly by branches of the neighbouring mountain ranges. The Noric Alps, in the south, are the most formidable, and several of their pinnacles rise to the height of 9000 feet. On the northern side, it borders on the Rhenish chain of the Wasgau, on the Thuringian and Bohemian forests. The Spessart, the Stugerwalde, and the Fichtelgebirge are found in the interior of Franconia along the Mayn. Between those mountains there are not only broad valleys, but even extended plains, especially along the banks of the rivers, though a considerable part of these are covered by morasses, overgrown with rank grass, and not yielding even turf. The greatest rivers of Germany water Bavaria: the Danube intersects the chief portion of it; Franconia is traversed by the Mayn,

and the Rhenish territory by the Rhine. The Danube receives from the Tyrol important tributaries, the Lech, the Iller, and the Iser. After every deduction, Bavaria is a very fruitful region; but culture is in an extremely unprosperous state. The cultivators are superstitious, and wedded to old habits; and they are so bound down by servitudes, *corvées*, and restrictions originating in the feudal system, as to discourage all their efforts. The legislature, however, has been very anxiously seeking to diminish these burthens, by commuting them for a regular rent or price. There are many fine corn-lands, and the wheat of the Danube is very good; but the produce is not, on the whole, sufficient for the supply of the inhabitants. Cattle are extensively reared, and their number is said to exceed 1,000,000: but the breed is little attended to; and, in case of sickness, the husbandmen, instead of applying remedies, lead them in pilgrimage to some favourite shrine. In 1821, there were 30,000 of these cattle pilgrimages. Horses and sheep are fewer in number, and of still worse breed; but the hog, yielding a favourite dish, is reared with very anxious care: in 1794, there were 400,000 hogs in the kingdom. A good wine is produced on the banks of the Mayn, to the extent of 600,000 or 700,000 eimers, of which part is taken off by Saxony. Timber is a national staple, a great part of the kingdom being covered with natural forests; oak and beech on the plains, pine and fir on the mountains. The Bavarian minerals are salt and iron. The salt mines of Ruchenhall, Traunstein, and Rosenheim produce 40,000 tons; those of Berchtoldsgaden 15,200 tons. The iron mines yield 32,000 tons. There is also a considerable supply of coal on the Rhine and on the Mayn. The manufactures, which are slender and coarse, are established almost exclusively in the newly acquired free cities. Even linen, the German staple, is in its infancy; but there are quantities of coarse woollens and of cotton goods, almost sufficient for internal supply. There is a great quantity of leather, of very coarse paper, and of fine works in gold and silver: these last chiefly at Augsburg; also a good deal of glass. Bavarian brandy and beer are reckoned excellent. The limited commerce of Bavaria is carried on chiefly by the Danube on one side, and the Rhine on the other. It exports salt, iron, wood, cattle, leather, paper, glass, and wine; receiving in return colonial produce and fine manufactures of every kind.

2945. *In regard to its political and civil state*, Bavaria, since 1818, has been a constitutional monarchy. It is represented by an assembly divided into two chambers; the lower contains a representative for every 7000 families. The king is obliged to assemble them only once in three years. The regular army consists of 36,500 infantry, 6400 cavalry, and 3350 artillery. It is raised by a conscription, including all between nineteen and thirty. There is also a strong reserve and *landwehr*. According to official documents, the population amounted, in 1825-26, to 4,037,017; of whom 2,880,383 were Catholics, 1,094,633 Protestants, 57,574 Jews, and a few other sectaries. (See *antè*, p. 678.) Bavaria, at least the original territory, has not ranked among the enlightened countries of Germany; but great efforts are now made to extend and improve the means of education, especially for the lower classes. There are three universities and nine lyceums, but mostly in the free cities and other acquired territories. The collections, however, made by enlightened princes are munificent, and on a greater scale, compared with its resources, than those of almost any other state. The library, of 400,000 volumes, contains many valuable manuscripts and early printed works; the picture gallery, chiefly removed from Düsseldorf, is also most splendid; and there are several of both, on a smaller scale, in the other cities.

2946. *In regard to local details*, the princes of Bavaria appear to have studied to obliterate the former political distinctions, and have distributed the state into eight circles, founded upon its grand natural feature, the rivers. There are two belonging to the Danube, Upper and Lower; two to the Mayn; to the Rhine, the Iser, the Rezat, the Regen, one each. A statistical view of these circles has already been given.

2947. *Munich*, the capital, lies in an extensive plain, on the Iser; and though it cannot boast any thing which suggests ideas of grandeur, either ancient or modern, it is handsome, and full of well-built modern houses; the streets are broad and well paved. Hassel ranks it among the handsomest cities in Germany. But the cathedral of Notre Dame, though of vast extent, and with towers 350 feet high, is declared by Mr. Dibdin to be frightful in the extreme, built of red brick, without ornament, design, or expression, and not of earlier date than the fifteenth century. The church of St. Michael, in which the public library is deposited, is more elegant, and its interior is one of the finest in Europe. The palace has also been considered a good specimen of modern architecture. The six suburbs comprise nearly half the town, containing 1419 out of the whole number of 3613 houses.

2948. *There are other ancient, venerable, and important cities* in Bavaria. Augsburg (*fig.* 385.), three centuries ago, outshone all the others, being the chief seat both of merchants and nobles. A thousand flags then floated from the castellated mansions and along the almost impregnable ramparts. Augsburg was once the chief seat of painting in Germany, the birthplace of Hans Holbein and other eminent artists, as is still attested by the exterior walls, covered with landscapes and groups of figures, executed in brilliant colours, though somewhat Gothic in design. The streets, like those of other old cities, are narrow and crowded, and the handsomest are in the suburbs, beyond the now-decaying walls. The town-house, however, is the finest in Europe. There is still an extensive and curious library, and a picture-gallery of some value, though many of its best specimens have been transported to Munich. Augsburg is still distinguished for its calico-printing,

which, in 1805, employed 6938 persons; for its gold and silver lace, for its mathematical instruments; and for its trade, which employs 2000 houses, and amounts to about 2,000,000*l.* sterling. Nuremberg, once the boast of

AUGSBURG.

ancient free city, with a castle, once distinguished by its strength, and a flourishing university. Würzburg is a city of similar character, celebrated as a strong fortress, and possessing an university, the medical

RATISBON CATHEDRAL.

school of which is distinguished all over Germany. Schweinfurt was likewise distinguished, during the thirty years' war, as a grand military position. Regensburg, which we call Ratisbon, was a Roman city, and, in modern times, venerated as the seat of the Germanic diet; the house used for which purpose still remains, but bears few marks of that dignified destination. Its chief ornament is the cathedral, which forms an ancient and noble Gothic structure (*fig. 386*). The streets are narrow and winding, but clean, consisting of high well-built houses. It suffered severely during the five days' battle in 1809, between the Austrians and the French. It still flourishes by a very extensive trade on the Danube, being the chief intermediate port between Ulm and Vienna. Landshut is a neat small town, with an extensive and very curious library. Nordlingen, only a moderate town, is celebrated in military history for several remarkable battles. Anspach and Bayreuth, once the seat of little courts, still hold a place as the capitals of circles. Passau is distinguished for its antiquity, its romantic site, and the treaty signed there, in 1532, between the Catholics and Protestants.

2949. *Wirtemberg* does not follow Bavaria in the order of magnitude; but we shall here notice it as completing the principal southern states. *Wirtemberg* occupies the greater part of the circle of Swabia; having Bavaria on the east, and Baden on the west. It is entirely traversed, from north to south, by the Neckar, which, rising in the Black Forest, and flowing due north, falls into the Rhine at Mannheim; and by the Upper Danube, which, rising from nearly the same source, directs its course north-east, till it passes Ulm and enters Bavaria. The mountains nowhere rise to an alpine height: on the western border is the Black Forest; but none of its branches within *Wirtemberg* reach above the height of 3000 feet. There is no part of the kingdom to which the name of plain can apply; but there are very broad and productive valleys; rendering *Wirtemberg*, on the whole, one of the most fertile countries in Germany. It is reckoned to contain 1,840,392 acres of arable land, 620,477 pasture, 79,296 of vineyard, and 1,735,466 woodland. The produce of grain of every kind, including maize, is computed at 6,000,000 bushels; of wine, 160,000 eimers: apples, pears, potatoes, and garden stuffs are plentiful and excellent. The rearing of cattle, with that of sheep, holds a very prominent place in the agriculture of *Wirtemberg*, and has lately been much improved both by new breeds and by artificial grasses and stall-feeding. In horses, hogs, and bees, this country is below the general level of Germany. Geese are reared in surprising numbers, and are sent even to Vienna and Italy. The extensive forests are valuable not only by their timber, but for producing cherries and several kinds of berries, which are a considerable resource to the poor as food, and from which spirituous liquors are extracted. The mines consist chiefly of iron, to the extent of 3000 tons, and of some salt. The manufactures are limited: they consist chiefly of linen or woollen, carried on by the rural population for home use. There are, however, 104,000 incorporated tradesmen. The commerce is brisk. The export consists in a large quantity of cattle, some grain and timber, some coarse woollen and linen stuffs, and manufactured tobacco. The returns are in colonial goods, cotton, silk, and other manufactures. The government is now the most decidedly constitutional of any in Germany; the nation being represented by states, which assemble every two years, are freely elected, and enjoy all the attributes proper to such institutions. The king of *Wirtemberg* has always been the most intractable in regard to the arbitrary measures of Austria and the Diet. In no country is there a more general diffusion of knowledge. It has one flourishing university; and its

the free cities of Germany, and the grand seat of its arts, both useful and ornamental, is now annexed to Bavaria; a change indignantly felt by its ancient and opulent burghers. Its churches and public buildings are still esteemed fine specimens of its ancient art: they are adorned with rich early paintings on glass, and select works by Albert Durer, a native of the town, and others by Sachsens, Behaim, and Pirckheymer. Nuremberg is above all famed for its inventions: those of the watch, the making of brass, copperplate engraving, the pedal, the musket, the trumpet, the clarionet, are all claimed for one or other of its citizens. The streets are broad, with many fine old houses, but not regularly built. The town-house, and several of the churches, are distinguished, the latter especially, for their paintings in glass. Bamberg is also a very handsome and

Würzburg

Wirtemberg

schools and seminaries of other descriptions are said, by Hassel, to be more numerous than in any other country of the same dimensions.

2950. *Wirtemberg* is divided into four circles, marked by natural features. 1. Circle of the Neckar, comprising the course of that river, the finest part of Wirtemberg. 2. Circle of the Black Forest, being the territory covered by that range of mountains. 3. Circle of the Danube. 4. Circle of the Jaxt, deriving its name from a small river of that name, and occupying the south-eastern part of the kingdom. The population in 1828, was reckoned at 1,520,000.

2951. *Stuttgart*, the capital, is situated on an extensive plain, 700 feet above the level of the sea, and surrounded on three sides by mountains. It is described as large and dull; but the streets are broad and well paved, especially the principal one, called the *Königstrasse*. In its nine squares and eighty-seven streets there are a number of handsome houses, and the new royal palace is elegant; but there are no monuments of antiquity, no objects calling up any grand historical recollections. There is, however, a library of 200,000 volumes, including 12,000 bibles, and a celebrated gymnasium, attended by 545 scholars. The manufactures and trade are of little consequence.

2952. *Among the other cities*, Ulm, in the circle of the Danube, may take the lead. This once great imperial city is happily situated in an exceedingly rich and beautiful plain, at the point where the Danube, swelled by the Iller and the Blau, becomes a great navigable stream. It retains, however, but a shadow of its once extensive industry, chiefly in linen manufactures, which now employ only 300 persons. The houses are built in the old German style, with high gables; the streets are irregular, but well paved. The chief ornament of Ulm is the cathedral (*fig. 387.*), one of the grandest structures of the kind in Europe. It is described

387

ULM CATHEDRAL.

by Mr. Dibdin as "English-looking;" broad, bold, and lofty, in a massive and imposing style of architecture. It is 416 feet long, 160 broad, and the tower 337 feet high. The interior is very noble, and adorned with many pictures of the old German masters. Ulm derives a dark celebrity from the overthrow and surrender of the Austrian army, under Mack, in 1805. There are still remains of the strong walls by which it was once defended. Halle is another free city of Swabia, different from one of the same name in Saxony. It is strongly fortified, and its town-house and the cathedral of St. Michael are greatly admired. There are very extensive saltworks, yielding 5000 tons of rock salt; also a trade in corn, cattle, and wood. Heilbronn is a strong little town, situated on the Neckar, in a fine wine country, and carrying on some branches of industry. Ludwigsburg, pleasantly situated on the same river, is the occasional residence of the royal family. Tübingen, in the Black Forest, contains the national university, with five faculties, attended by 557 students.

2953. *The grand duchy of Baden* consists of the long valley of the Rhine, from Basle to Mannheim, sloping down from the Black Forest, which borders it like a ring. Its surface, of about 6000 square miles, contains no plain, but a number of broad fine valleys subordinate to the great valley, among which the Murgthal and the Kinzigtal are the most important. The mountains of the Black Forest nowhere rise much above 4000 feet,

and their heads are not covered with snow more than half the year: they abound, as their name implies, with dark and majestic woods. The soil in the lower valleys is every where fertile in the extreme, and the richest pasture covers the sides of the hills. The Danube rises from three springs near Donaueschingen, but leaves the territory while yet little more than a brook. Of far greater importance is the majestic circuit made by the Rhine along the whole southern and western border. The lower course of the Neckar also flows through Baden; and numerous small but fertilising streams descend from the Black Forest into the Rhine. Grain is produced so abundantly as to afford a surplus for exportation: the wheat yields a very fine flour, to which we may add the finest hemp in Germany, and excellent tobacco. Pulse, flax, and hops are less productive. Fruits are very abundant, though not in the same vast profusion as in Wirtemberg. The vineyards along the Rhine and the Neckar are extensive, and enjoy a high reputation; but the produce of the territory on the Lake of Constance, or Bodensee, called sea-wine, is much less prized. The number of horned cattle is great, amounting to 400,000 head; and the hogs are estimated at 194,000: but horses and sheep are not reared with the same success. Although the range of the wild animals has been much diminished, yet, in the recesses of the Black Forest, the wild hog, the stag, and the fox, afford still too much scope for the amusement and occupation of hunting. The forests of noble trees afford a most valuable commodity, of which a great quantity is sent down the Rhine to Holland. The mines of silver, copper, iron, and salt are pretty considerable; none of them very great. The manufactures are but of very limited extent, though they include many fabrics of wood, particularly clocks, to the great number of 107,000; also 51,000 dozen of metal spoons. Linen employs about 10,000 persons. Baden enjoys a great transit trade, from its situation along the Rhine and on the frontiers of Germany, France, and Switzerland; it has also a regular trade in the export of its own wood, wooden clocks, fruits, grain, and wine. Mannheim is the chief emporium.

2954. *The population of Baden* was found, in 1819, to be about 1,100,000; and it had increased in 1828 to 1,130,000, notwithstanding considerable emigrations to Russia and America. There are supposed to be 663,000 Catholics, 248,000 Lutherans, 82,000 Calvinists, and 15,000 Jews. Since 1817, Baden has had a representative constitution nearly similar to that of Bavaria and Wirtemberg. The revenue may amount to between 5,000,000 and 6,000,000 guilders; but it is burdened with a debt of 20,000,000. The standing army is from 8000 to 10,000, with about an equal number of landwehr; to which may be added the landsturm, or levée en masse, which may amount to about 100,000. The establishments for education have recently been very extensive: there are two universities, four lyceums, and thirteen gymnasiums.

2955. *Carlsruhe*, as a capital, is small, being supported almost entirely by the residence of the court, and of the gay and wealthy classes of society, whom that residence attracts: this gives it a very lively aspect; yet though it contains many good houses, and thirteen which rank as palaces, its aspect, according to a late traveller, is only that of a very large and handsome country village. It has a fine lyceum, and several scientific collections and establishments, though not on a very great scale.

2956. *Baden possesses other equally important cities.* Mannheim, at the junction of the Neckar and Rhine, is reckoned one of the finest in Germany; but it seems agreed that it is too mathematically regular, all the streets crossing each other at right angles, and every house being of the same height. An extensive and strong castellated palace extends along the Rhine, and contains a handsome collection of antiquities, casts, drawings, paintings, with remains of the ancient library, amounting still to 70,000 volumes. Heidelberg is one of the most ancient cities of Germany; and above it the ancient palace of the electors palatine still frowns, a huge majestic pile; though the mass of its walls lies in fragments in the ditch beneath. Its cellars still

contain the famous and enormous Heidelberg tun, capable of holding 500 pipes of wine, but now empty. The most ancient German university, founded in 1386, still flourishes under royal patronage, and had, in 1818, 45 professors and 603 students. Philippsburg, once among the strongest fortresses of Europe, has been dismantled since 1802. Rastadt, famous in the annals of diplomacy, is only a small country town. Baden, encircled by seven lofty fir-clad hills, attracts strangers by the beauty of its situation, and still more by its warm baths, which make it at once the resort of the sick, the fashionable, and the gay. Kehl, opposite to Strasburg, is an important military position. Freyburg, a considerable town, in the heart of the Black Forest, has a well-endowed university. Constance, situated on the lake of the same name, where the Rhine issues from it, has a little trade and shipping, raises a great deal of pulse and vegetables in its suburbs, and in its vicinity a good deal of indifferent wine.

2957. *The kingdom of Saxony* now consists of a much diminished part of the former possessions of that great house, which once held the chief sway in northern Germany. The policy of Napoleon, indeed, raised it to a greater magnitude than it had ever before possessed, by annexing part of the Prussian territory, with a considerable portion of Poland, under the title of the duchy of Warsaw. But of all these acquisitions Saxony was stripped, in consequence of her adherence to Napoleon at the time of his downfall. The kingdom now consists of the plain of the Elbe, extending along its course for about a hundred miles after it forces for itself a channel through the mighty rock wall of the Erzgebirge, which separates it from Bohemia. On this line it receives several fine tributaries; the Mulda and the White Elster from the west, the Black Elster from the east. The eastern borders of Saxony are watered by the Neisse and the Spree: on its frontiers are several chains of mountains; the Erzgebirge on the south, a rich metalliferous range; the Riesengebirge in Swabia; the Vogelberg and Thuringian forest in the west. The central plain is fertile, and the most thoroughly well cultivated in all Germany; notwithstanding which it cannot fully supply with bread the dense manufacturing and mining population. A great part of the surface also is covered with flocks of sheep, to the number of 1,300,000, the wool of which has been raised to high perfection by the introduction of the merino breed. The woods are extensive; but, since the loss of the vast forests of Lusatia and Thuringia, they are not adequate to the supply of the mines and manufactures. The mining operations, though in the hands of government, are conducted with a science and a diligence not equalled in any other part of the world. Their products are, silver, 48,000 marks; lead, 10,400 cwt.; cobalt, 8900; tin, 2400; copper, 600; iron, 24,000 tons. Saxony surpasses all the rest of Germany in manufacturing industry, which is supposed to occupy three-fifths of the inhabitants. The staples of linen and woollen are both considerable; but it is in cottons that this country excels all the rest of Germany. Hassel hesitates not to assert that the Saxon ginghams and muslins are equal in every respect to the English, and that, if they cannot support the competition, it is only because the latter are more slight and showy. There is a great deal of paper manufactured, and printing is conducted upon a large scale. The metals of Germany are smelted with the same skill with which they are extracted; and the porcelain of Dresden and Meissen rivals that of China. The commerce of Saxony is particularly active, not only in its own productions, but as it contains in Leipzig the grand centre of all the commercial movements of Germany. The whole book trade of this vast country is carried on there; independent of which, the other goods brought to its three fairs are estimated at 18,000,000 rix-dollars. The trade of Leipzig, and of Saxony in general, is carried on chiefly by waggons, though a good deal also goes along the Elbe.

2958. *The population of Saxony*, in 1828, was rated at 1,400,000. Lutheranism, which was first established here, is almost universal, there being only 40,000 Catholics; though, by a singular anomaly, the king himself is of that persuasion, and has obtained, since 1811, complete equality for those of his own creed. The diffusion of knowledge is general; but there is only one university, that of Leipzig: and the schools are said to be on a contracted scale, and the attempt to improve them has been hitherto ineffectual. Saxony retains still an ancient constitution, but on the feudal model, and the states consist merely of the nobles and corporations: the peasantry are not represented, and are encumbered with a very disproportionate share of the public burdens.

2959. *Dresden* (fig. 388.), though not one of the largest, is generally reckoned the most elegant of the German cities: it has even been called the Florence of Germany. It is

388

almost unrivalled in situation, the country around presenting a mixture of romantic natural scenery, with the richest possible cultivation. The banks of the Elbe are on one side abrupt, rocky, woody, picturesque; on the other, they swell into graceful and verdant eminences. The streets of the old town are somewhat narrow, but bordered by many lofty palaces of the Saxon nobles, built in a simple and austere style of architecture. The royal palace is of great extent, and contains many

elegant features; but these are so various and scattered, as to produce nothing striking as a whole. The new town, on the opposite bank, is built in a lighter and more regular style, and has one very fine street; but it cannot vie with the magnificence of the opposite city, which remains still the seat of the court and the fashionable circles. The stone bridge, of eleven arches, over the Elbe, is the finest structure of the kind in Germany. Dresden is illustrious for its collections in literature and the arts. The royal library is one of the first in Germany, and the picture-gallery has no rival on this side of the Alps. There is also an immense and valuable collection of prints, of casts, and of antiquities.

* 2960. *Among other towns* is Meissen, a little city, above the Elbe, which gives name to the circle, adorned with a handsome cathedral, and a ducal castle, majestically seated on a rock of granite. It is now converted into the royal manufactory of porcelain, producing the finest specimens of that article in Europe. Freyberg, the capital of the mining district in the Erzgebirge, the scene of the most extensive mineral operations, is rendered illustrious by the residence and instructions of Werner, the founder of the modern school of mineralogy. Chemnitz, which may be held as the manufacturing capital of the same district, employs 1600 looms in linen and cotton, and makes 50,000 dozen stockings. Bautzen, or Budissin, the capital of Saxon Lusatia, is a well-built and flourishing town, carrying on a great variety of manufactures, stockings, gloves, hats, woollen cloth, &c. Zittau is also considerable, as being the centre of the yarn and linen trade. Königstein, on a high rock over the Elbe, deserves notice, as the strongest fortress of the monarchy.

2961. *Leipzig* claims distinguished notice, as the grand centre of commerce, not only for Saxony, but for all Germany. The scene which it presents of bustle and business, though familiar to an English eye, has no parallel on the Continent. "Such mountains of wool-packs, such firmaments of mirrors, such processions of porters and carters, are to the German a new world." In its structure, it presents a mixture of the old and new style of building, which is singular, but not displeasing. The whole wears an air of comfort and substantiality, which accords with the character of the place. The surrounding country is fertile and well cultivated, but flat and monotonous. It has, however, been the scene of some of the most signal events in European military history. Here Gustavus Adolphus gained that signal victory which turned the tide of fortune in the great protestant war; and at Lutzen, nor far distant, he fell, crowned with victory. A number of unhewn stones, standing horizontally, mark the spot, on one of which is rudely carved, "Gustavus Adolphus, king of Sweden, fell here, for liberty of conscience." This "stone of the Swede," as it is called, though in a field by the road, has remained untouched. Round and in Leipzig, too, was fought that mighty battle which liberated Germany, and drove Napoleon beyond the Rhine. The inhabitants, who call this "the battle of the people," have carefully preserved the traces of the cannon and musket-balls with which many of the buildings were struck or perforated.

2962. *The kingdom of Hanover*, which, for more than a century has been an appendage to the crown of Great Britain, occupies, with some intervals, the whole north-western angle of Germany, from the Elbe to the frontier of Holland. It contains a surface of about 15,180 square miles. The Hartz, a long chain of detached mountain masses, extending for more than 100 miles along its southern border, is covered with extensive woods, and rich in mines. Its highest pinnacle, the Brocken, does not fall within Hanover; but there are several heights somewhat exceeding 3000 feet. The rest of the kingdom forms the commencement of that immense plain which extends across Europe to the Urals, or mountain boundary of Asia. This plain consists of a continuous basis of sand, interspersed with blocks of granite, which seem to have been carried thither by some ancient revolution of the globe. The land, where it is not brought under cultivation, is only an expanse of heath and gloomy pine. The only fertile tracts are along the banks of the rivers, and on the flat coast of the sea, where artificial mounds have rescued from its ravages an expanse of very rich meadows. The country has the Elbe for its eastern boundary, and is traversed by the navigable streams of the Ems, the Weser, and their tributaries; so that it enjoys great advantages for trade. The disadvantages of nature are not redeemed by human diligence to the same degree as in some other parts of Germany. It is true, that in Göttingen, Hildersheim, Grabenhagen, and some of the marshy tracts redeemed from the rivers and from the sea, both skill and diligence are displayed. But others, as Luneburg, Hoya, Osnaburg, &c., which might at least be greatly improved, are left a dreary and savage waste, the inhabitants preferring to hire themselves as servants to the Dutch. After all, grain is raised sufficient for internal consumption, and cabbage and other vegetables more than sufficient. Great quantities of flax are reared for its linen manufactures. With respect to live stock, Hanover is only distinguished for its hogs, which possess a peculiar excellence, rendering Westphalia hams famous over the globe. The supply of timber is large, and in some provinces there is great abundance of turf. The mines of the Hartz are very valuable, being in annual amount about 2,000,000 rix-dollars; of which silver averages 410,000; lead, 258,000; copper, 44,000; iron, 395,000; brass, 94,000; zinc, 45,000; salt, 548,000; and some coal. Coarse and household linen is the staple manufacture, to which is added some fine linen, and a good deal of sailcloth. Brewing, which was formerly very extensive, is now much fallen off, and distillery has sprung up in its stead. The commerce for which this part of Germany is favourably situated has been chiefly engrossed by the Hanse towns of Hamburg and Bremen; while most of the interior trade passes by Brunswick. Emden, in East Friesland, is almost the only port from which there is any foreign trade; while the waggon traffic passes chiefly through Luneburg and Münden. The population of Hanover amounted in 1828 to 1,550,000. It was occupied by Bonaparte during the war; and, on its restoration, in 1815, was erected into a kingdom, a name, perhaps, necessary, instead of the lost title of electorate; but as the sovereign, since 1714, has held his seat in London, the immediate rule is by a regent. The government, in 1815, also received a constitutional form; and states were organised: they are composed of 101 deputies, of whom 10 are prelates, 49 nobles, and 42 deputies from the cities. It has been remarked, however, that this representation is not on the most liberal principle, being confined to the nobility and the corporations, and excluding almost entirely the body of the peasantry. Each of the numerous and once separate districts of which Hanover is now composed, has also a constitution of its own, and peculiar modes of administering justice.

2963. *Among the cities, Hanover, the capital*, is a plain, ordinary town, situated in the midst of the wide sandy plain, and neither very large, nor containing any thing very remarkable. It is supported by the residence of the court and military, and the occasional assemblage of the states; and, notwithstanding the close connection with England, English manners have not made much progress. There is a library and collection of paintings, but both on a small scale. Göttingen possesses a greater interest, as the seat of the most flourishing protestant university of Germany, supported by the Hanoverian government with an almost unrivalled liberality. The number of students, which in 1817 amounted to 1065, has now increased to 1500: it is the

ambition of every German youth to study at Gottingen, and of every German *savant* to be one of the professors. The government pays to the latter a salary of not quite 200*l.* a year, which, however, is more liberal than any of those allowed in other German seminaries; and it expends more than 1000*l.* a year in supporting a library of nearly 300,000 volumes, said to be the most useful in Europe, being supplied with plain editions of all new works of importance, without any expenditure incurred for show and ostentation. The professors amount to forty, with a number of private teachers and tutors. Luneburg, on the Ilmenau, where that river is navigable for vessels of sixty or seventy tons, has a pretty brisk trade, especially by land, employing 70,000 horses and forty waggons daily. Munden, at the junction of the Weser, Fulda, and Werra, receives annually 600 vessels into its port. Clausthal is an industrious manufacturing place.

2964. *Hesse-Cassel* is a smaller state than those hitherto described, comprising only 4550 square miles, with a population of 592,000. It borders on Saxony, Hanover, Bavaria, and a crowd of little states. The country is almost entirely filled with hills and woods, presenting a very picturesque aspect; though, of the principal ranges, the Thuringian forest does not rise above 3500 feet, nor the Fulda range above 1500 feet, but both are covered with extensive forests. The Fulda and Werra, tributaries of the Weser, are the chief rivers, though it touches also on the Mayn. The land is cultivated with diligence, but not in an enlightened or improved manner, being too much subdivided among a poor peasantry. It yields grain, however, somewhat beyond its own wants, with large quantities of flax, and a profusion of valuable wood. It has 363,000 sheep, and 139,000 hogs. The produce of the mines is considerable, especially iron, with some silver and copper. The only flourishing manufacture is that of coarse linen, which is generally diffused throughout the district. Hesse carries on little trade beyond the export of the articles already mentioned, but it is situated on the passage between the inland trade of southern and of northern Germany, on which it is thus enabled to levy considerable tolls. Hesse-Cassel, which formed the central portion of Jerome Bonaparte's ephemeral kingdom of Westphalia, has now been restored to the elector, who represents the ancient powerful and warlike landgraves of Hesse-Cassel: there are states, but quite in the ancient and feudal form. The revenue is about 4,000,000 guilders. The army consists of 18,000 men, of whom 2000 are in regular pay; the rest are only called out during part of the year. Hesse no longer carries on that extensive traffic of mercenary troops, which formerly brought in large sums of money, and rendered the elector, perhaps, the richest individual in Europe.

2965. *Among the cities, Cassel, the capital*, is divided into two parts; of which the old town, extending along the Fulda, exhibits, in the extreme, all the defects of old German cities; yet it is still the scene of traffic. The new town, built in a higher situation, is one of the most elegant in the empire: the Königsplatz, of an oval form, with six streets branching from it, is said to be finer than any other of its squares. The palace, seated on a delightful terrace, and the museum, are also fine edifices. There is a library of 70,000 volumes, a fine gallery of paintings, and some other interesting collections. Two miles from Cassel is Wilhelmshöhe, an Ionic palace, with a long, lofty, simple front, very beautifully situated on the slope of a wooded hill. Its waterworks display great taste and variety. Hanau, at the junction of the Mayn and the Kintzig, is a large, well built, open town, carrying on a considerable trade. Fulda is an agreeable little city, finely situated on the river of that name, over which there is a handsome stone bridge.

2966. *Hesse-Darmstadt, called the Grand Duchy of Hesse*, is composed of two portions reaching along the Rhine from the Prussian to the Bavarian frontier. It is entirely enclosed by the Odenwald, the Vogelsberg, the Westerwald, and other mountains of this part of Germany, not lofty, but steep and wooded. The broad valley of the Rhine, however, with others branching from it, enclose a great extent of fertile territory, very productive, especially in wine, of which 64,000 tuns, according to Hassel, are annually produced; but oats are the only grain for which its high tracts are suited. Besides the Rhine, this duchy includes the lower part of the course of the Mayn, and even touches the Neckar. The entire surface does not exceed 1120 square miles. In addition to the above productions, tobacco and flax are raised in considerable quantities; and the hills are covered with large herds of cattle. There is a little copper, iron, and salt. The population is estimated at 700,000, of which only 140,000 are catholics. Hesse-Darmstadt has a constitution, which, after some difficulty, the grand duke was prevailed on to make sufficiently liberal. The revenue is about 4,000,000 guilders; and the army, independent of landwehr, amounts to 8000 or 9000 men.

2967. *Among the cities, Darmstadt, the capital*, is not the most remarkable, though it is handsome and agreeable, with 15,400 inhabitants, a splendid opera-house, and a library of 90,000 volumes. Darmstadt derives much greater lustre from Mentz, or Mayence (*fig. 389.*), that great imperial city, formerly the residence of an electoral bishop, which is now annexed to its territory. The fortifications of Mentz, which are of immense strength and extent, have been put in repair, and are now held by the diet as one of the great bulwarks of the empire. The troops of Austria and Prussia, therefore, occupy the forts in front of Mentz, and those of Cassel on the opposite bank; while the duke governs the interior of the town. The Rhine is here crossed by a bridge of fifty-two pontoons. Mentz has now few manufactures, but a very considerable trade in wine and colonial produce. Worms, another once great imperial city, exhibits only the ruins of its former state, and is almost choked with rubbish, the fruit of successive desolating wars. It has still the remains of some fine edifices, and a good fruit and corn market. Offenbach, a thriving little town, is the only place in the duchy where manufactures flourish.

389

MENTZ.

2968. *A variety of little states and principalities* are clustered in different parts of the north and west of Germany. These, in extent, and even in revenue, are often inferior to the estates of English nobles even of a secondary class; yet the petty princes by whom they are ruled maintain all the form and state of sovereigns. They have states, ministers, an exchequer, a public debt, an army, all in miniature. Yet, small as these princes are, circumstances have occurred to draw them into considerable notice in the eyes of Europe. Several, in the absence of wealth and power, have endeavoured to distinguish themselves by personal merit, and particularly by military talent: Brunswick and other houses have produced some of the greatest European generals. The obligation, also, imposed upon the British royal family, of marrying only into protestant houses, with the inconveniences which might be produced

by an alliance with the great monarchies, has caused these smaller houses to be almost invariably resorted to when a matrimonial alliance was projected. Several of them have given queens to Great Britain; one of the smallest, but for a recent fatal event, would have given a matrimonial king. Similar connections have been formed with Russia and other northern courts. The following table, of the extent, population, &c. of these states, in 1830, has been drawn up from good authorities:—

	German Square Miles.	Population.	Revenue in Florins.
Saxe-Weimar	65.82	225,000	2,245,000
Saxe-Oldenburg	23.42	115,000	725,000
Oldenburg	116.	248,198	1,500,000
Saxe-Coburg-Gotha	48.88	145,500	1,180,000
Saxe-Meiningen	41.72	130,000	1,900,000
Mecklenburg-Schwerin	223.88	440,000	2,500,000
Mecklenburg-Strelitz	45.	70,400	700,000
Brunswick	70.37	244,200	3,089,000
Nassau	82.70	348,000	2,967,000
Anhalt (three principalities)	47.23	130,200	1,668,000
Schwartzburg (two principalities)	36.	106,000	650,000
Reuss (two principalities)	28.	81,700	608,000
Hohenzollern (two principalities)	23.37	53,000	270,000
Waldeck	21.66	56,000	480,000
Lippe-Detmold	20.50	76,718	580,000
Lippe-Schauenburg	9.75	25,500	240,000
Hesse-Homburg	7.84	21,350	110,000
Lichtenstein	2.50	5,800	20,500
Hamburg	7.10	150,000	1,800,000
Frankfort	5.	54,000	760,000
Lubeck	6.75	40,500	480,000
Bremen	5.	57,800	480,000

2969. *The grand duchy of Saxe-Weimar*, must rank with the small states, though it takes the lead among them. It stands chiefly upon the Thuringian forest, and is diversified with wooded hills of various height, form, and aspect. The soil is in many parts ungrateful, but is diligently cultivated, though by a poor peasantry, and in too minutely divided portions; notwithstanding which, it yields corn more than is sufficient for its own supply, and breeds sheep with very highly improved wool, which, under the name of electoral, is in request even in England. But the glory of Weimar consists in its intellectual eminence, which has rendered it the literary capital, the Athens, of Germany. While the other princes disdainfully neglected men of learning, or confined their patronage to the French, the grand duke of Saxe-Weimar, by extreme liberality and courtesy, drew round him all the great men by whom the annals of German literature have been illustrated during the last half century. Wieland, Herder, Schiller, Göthe, and a crowd of secondary name, have, successively or together, made Weimar their residence. This German Athens is little more than a spacious village, with scarcely a regular street: only the palace and house of assembly can be called spacious edifices. It has, however, a library of 110,000 volumes, liberally thrown open to the public. Every degree of freedom is given to the press that the great monarchs will allow; but to them the press of Weimar is an object of continual jealousy. The grand duke, the most liberal and popular of all the German princes, was the first to give to his subjects a representative constitution: yet so well were they before satisfied with his government, that attendance on the states was considered by some as an unnecessary burden. Jena, a small town, is distinguished by one of the most flourishing universities of Germany, and as the theatre of the great battle which overthrew for a time the Prussian monarchy.

2970. *Mecklenburg* is a territory of the most northerly part of Germany, north-east of Hanover, and bordering on Pomerania, of whose character it in a great measure partakes. It consists to a great extent of lake and forest; and the cultivation is comparatively rude; yet a variety of gentle hills give it a picturesque aspect. It is divided into the two grand duchies of Schwerin and Strelitz; the former is much the more extensive; and Schwerin, the capital, is a pretty considerable town, with a handsome palace, situated on a lake, and containing a good gallery of pictures. Rostock is a larger town, situated on the Baltic, and exporting grain to the value of from 150,000*l.* to 200,000*l.* Mecklenburg-Strelitz is exceedingly small, not containing quite 80,000 people, and its capital being little more than a large village; yet it is interesting to Britain, as having given to her Caroline, wife of George II., and Charlotte, wife of George III., two of the most respected British queens.

2971. *Brunswick* is the appanage of one of the greatest and most ancient houses of Germany, that of Guelf; whose head, Henry the Lion, contended with the house of Swabia for the empire, but was worsted, and put under the imperial ban. Since that time, the Guelf family has held only a secondary place in Germany. The branch of Brunswick-

Luneburg, however, has risen to the dignity, first of electors of Hanover, and then of kings of Great Britain. That of Wolfenbüttel hold only the small domain called the duchy of Brunswick. It is rather a productive territory, situated partly on the declivities of the Hartz, partly on the plain of Saxony. The city of Brunswick is larger than in proportion to the state, containing a population of about 30,000. It is a considerable seat of the inland trade of Germany, its fairs ranking next to those of Frankfort and Leipzig. The government was nearly absolute till very lately, when the people, by a violent change of dynasty, effected for themselves a representative constitution.

2972. *Branches of the house of Saxony*, once the ruling family in northern Germany, hold a cluster of small principalities to the west of Saxony royal. Saxe-Coburg-Gotha has been lately formed by the union of these two branches, on the extinction of that of Gotha. It comprehends a great part of the territory of Thuringia, and is rather productive. The city, containing about 12,000 inhabitants, is the channel of a considerable trade connected with the fair of Leipzig. It is somewhat a learned city; containing a library of 60,000 volumes, with valuable manuscripts. Saxe-Coburg is a mountainous territory, comprising part of the Thuringian forest. It contains good pasturage, and some valuable mines. This territory has been raised to distinction by the good fortune of one of its younger members, now king of the Belgians. Saxe-Meiningen, on the Werra, is a little tract, enriched by mines of salt at Salzungen, and by some of coal, iron, and cobalt. Saxe-Hildburghausen is the most complete example of one of these petty principalities. With a population of 32,000, and a revenue of 20,000*l.*, it has all the appendages of a great state; a public debt, an army of 100 men, and a vote in the Germanic diet.

2973. *Oldenburg* is distinguished by the high rank of its princes, connected by family alliances with all the great powers of the north, particularly Russia. The duke has possessions in different parts of the north of Germany; but the main part of them is situated on the Weser, to the west of Hanover; a flat, marshy district, but abounding in rich pastures, and somewhat resembling Holland.

2974. *Nassau* is a dukedom, which, by the union of the territories held by several branches of the same family, has attained to some tolerable magnitude. Situated in the southern part of Franconia, forming a hilly country on the banks of the Rhine and the Mayn, it produces those valuable wines, old Hock and Bleschert, which distinguish this part of Germany: it does not contain, however, any towns of importance.

2975. *The other principalities* are all very small. Anhalt, on the Elbe, between Saxony and Brandenburg, has its population, of 130,000, divided between the three branches of Dessau, Bernburg, and Köthen. The family is ancient, and has produced some men of eminence. *Schwartzenburg*, a district of Franconia, has 106,000 people, divided between the two branches of Sondershausen and Rudolstadt, both of great antiquity, and deriving more importance from their great estates in Bohemia and other parts of the Austrian territory. *Reuss*, in Upper Saxony, has 81,700 inhabitants, divided between the elder and younger branches. *Lippe-Detmold* and *Lippe-Schauenburg* are situated to the south of Hanover; the one hilly and wooded, the other flat and fertile. A former prince of Lippe-Schauenburg made a distinguished figure in the service of Portugal. There are two princes of Hohenzollern, Sigmaringen and Hertzogen, having between them 53,000 people. They form the only petty states in the south of Germany, being situated in Swabia, between Baden and Wirtemberg. Waldeck-Pyrmont, composed of two hilly counties between Hesse and Hanover, derives almost its sole importance from the mineral baths of Pyrmont, which are among the most celebrated in Europe. Hesse-Homburg is a small mountainous principality, near Frankfort, possessed by a branch of the family of Hesse-Darmstadt. Though, by the favour of the house of Austria, its possessions have been tripled, they do not exceed those of a rich English squire. Homburg, the capital, is a small town, in a very picturesque situation. Finally, the minimum of principalities is found in *Lichtenstein*, a district in the Saxon Erzgebirge, with only 5800 inhabitants; but the prince, as an Austrian nobleman, is one of the most opulent individuals in Europe, and his family distinguished by information and intelligence.

2976. *The four free cities of Germany*, Hamburg, Lubeck, Bremen, and Frankfort, form still an interesting feature, necessary to close the picture of this great country. They are the sole remnant of the Hanse Towns and imperial cities; illustrious confederacies, which, during the middle ages, acted a most conspicuous part in the improvement of the European system. The members of the congress of Vienna, though little friendly to any thing republican, considered these so fully established, and so venerable by antiquity, that they sanctioned them as a part of the Germanic body.

2977. *Hamburg* is the most important commercial city of Germany. It forms the emporium of Saxony, Bohemia, and other fertile and industrious regions watered by the Elbe and its tributaries. It is, at the same time, a grand medium of communication between the northern and middle states of Europe; and a species of *dépôt* for the commodities of each. The city is of great antiquity, having been founded by Charlemagne, as a bulwark against the rude northern tribes, by whom it was repeatedly sacked, particularly by the Vendes, in 1002.

Its advantageous situation, however, enabled it always to recover and extend its commerce, till, in the middle of the thirteenth century, it concluded with Lubeck a treaty, which became the basis of the celebrated Hanseatic League. It continued in a state of uninterrupted advance, while other members of the confederacy declined. In 1618 it was declared a free imperial city, and in 1768 was emancipated from every remnant of dependence upon Denmark. In 1807, however, a period of deep calamity commenced: it was forcibly occupied by the French troops, and Bonaparte seized on a part of the public treasure. He caused a still more deadly injury by the enforcement of the continental system, by which the mercantile interests of Hamburg were reduced almost to a state of ruin. She suffered also severely in 1813, by a premature attempt to effect her liberation: but, on the downfall of Napoleon, she was restored to all her rights, and has regained her former importance.

2977. *Hamburg*, commanding the navigation of the Elbe and its tributaries, is almost the sole channel for the trade of central Germany, and is thus, perhaps, the greatest commercial city on the Continent. She exports the linens of Silesia, the wool of Saxony, grain in abundance, though inferior to that of Poland, woodwork, flax, rags, spelter, and some wine. Her warehouses contain also abundance of Baltic produce, which can be obtained at moderate rates. Her imports consist of British manufactures, colonial produce, wines and other liquors, cotton, indigo, and dyewoods. In 1832, there were imported 47,250,000 lbs. of coffee, 100,750,000 lbs. of sugar, 103,000 pieces hides, 5,250,000 lbs. of rice, 1,500,000 lbs. of pepper, 36,828 bales of cotton, 5297 hogsheads of tobacco, 8054 chests of indigo, and 5593 puncheons of rum. No regular account is kept of exports and other imports; but, from the produce of the very moderate duty of less than 2-5ths per cent., Mr. McCulloch estimates the total amount of both rather to exceed than to fall short of 14,000,000*l.* sterling; and nearly the whole of this immense commerce is in the hands of Britain.

Hamburg is not a well-built town; the streets being in general narrow and irregular, the houses constructed of brick or wood. The churches of St. Michael's and St. Peter's have elegant spires, and the new exchange is handsome; but there is no edifice distinguished for its splendour. The hospital, however, completed in 1823, is most spacious and commodious, being 700 feet in front, and each wing 300 feet long. It is extremely well managed, and believed to contain 2500 beds. The executive in Hamburg consists of a self-elected senate of twenty-eight members, who, however, are checked by popular councils chosen by all who have 240*l.* of property within the city. According to Dr. Buck, the average population between 1817 and 1826 was 122,815; while Crome estimates that of the whole territory at 150,000.

2978. *Lubeck*, as a Hanse town, rose to distinction as early as Hamburg, and possessed even a pre-eminence; the maritime law by which the concerns of that great confederacy were regulated having derived its name from this city. Its situation, however, within the Baltic, and not commanding the navigation of any great river, rendered it impossible for it to compete with the high prosperity to which Hamburg has reached in modern times. It acquired celebrity by the retreat of Blucher, after the disastrous battle of Jena; when that general, entrenching himself in the city, made a desperate stand against a superior force of French troops, in which Lubeck suffered severely. By the treaty of Vienna it regained its privileges as a free city, and a place in the Germanic diet. Its commerce is impeded by the small depth of water in the Trave, upon which it is situated, and which obliges vessels drawing more than ten feet to stop at Travemunde. What remains of its commerce consists in the export of the grain abundantly produced in the surrounding countries; for whose use it imports wine, colonial produce, and manufactured articles. Lubeck, for an old town, is well built of stone, and the church of St. Mary is elegantly adorned with a series of paintings called the Dance of Death. The fortresses, once of great strength, were demolished by the French.

2979. *Bremen*, at the mouth of the Weser, is enriched by the commerce of that important river, down which are brought the productions of Westphalia and part of Franconia; countries extensive and valuable, though not nearly equal to those watered by the Elbe. The city is situated on both sides of the river. The old town consists of narrow streets, bordered by high gloomy houses, built in the fashion of the middle ages: but there is a new town, in a much more elegant style. The government, which once approached to an oligarchy, is now almost purely democratic. In 1829 there entered Bremen 881 vessels; of which 66 were from the United States; 45, West Indies, chiefly Spanish; 14, South America; 110, Great Britain; 37, France; 5, Spain and the Canaries; 2, Italy; 80, Russia; 11, Sweden; 11, Norway; 66, Denmark; 321, North of Germany; 41, Prussia; 70, Netherlands, &c.; 2, the whale fishery. The chief imports were coffee, 13,500,000 lbs.; sugar, 17,000,000; cotton, 1,500,000; tobacco, 14,000,000; wine, 15,000 oxhoft (58 gallons); grain, 5098 lasts.

2980. *Frankfort on the Mayn* is an ancient and venerable city, the seat of the Germanic diet. Its chief importance, however, is derived from being one of the great centres of the German inland trade: its fairs, which are held twice in the year, being second only to that of Leipzig. Its situation on the Mayn, near its junction with the Rhine, and at the meeting of the great roads which traverse Germany, is extremely favourable for this object. Though the houses are built of wood, there are several spacious squares and streets; also numerous large mansions which recall solemn historical recollections. The fortifications

are no longer of any importance. The main body of the city is on the north side of the river; but a portion, called Sachsenhausen, stands on the north side, and is connected by a stone bridge. The inhabitants are, in general, well informed; and many private individuals possess valuable libraries, and collections relating to the fine arts. The Jews, who are very numerous, were formerly confined to a particular quarter, where they were shut in every night; but since 1796 this illiberal system has been discontinued.

CHAP. XI.

HOLLAND AND BELGIUM.

2981. *The Netherlands*, comprising now the two kingdoms of *Holland* and *Belgium*, form a maritime territory, which, situated almost in the centre between the north and the south of Europe, and penetrated by the Rhine and its tributaries, possesses great natural advantages for industry and commerce. They have, accordingly, from a very early period of modern history, ranked as one of the most prosperous and flourishing parts of Europe. The union of the Batavian and Belgic Netherlands into one kingdom, though in fact only a renewal of that which subsisted at a former period, was suddenly terminated, in 1830, by a revolution of the Belgians. The separate existence, however, of Holland and Belgium being yet recent, and the statistical information respecting them having for a number of years been collected with reference always to the entire Netherlands, they will be still treated most advantageously in combination. It may be sufficient to observe, that, since the revolution of 1830, Belgium has been erected into a separate monarchy, through the mediation of the five great powers of Europe; and the crown, with their consent, has been conferred on Prince Leopold, formerly of Saxe-Coburg.

SECT. I. *General Outline and Aspect.*

2982. *Holland and Belgium* may be regarded as a large corner or segment cut off from France and Germany, which form round it a species of irregular arc. Arbitrary lines, drawn conformably to treaties, mark all except its maritime boundaries; for, though several of the greatest rivers of Europe cross its territory, none of them have any limitary character. The maritime boundary, which, like the inland, extends from north-east to south-west, is the North Sea, or German Ocean, which is formed here into a species of large gulf by the opposite coast of part of the English Channel. Holland is also penetrated by the deep inlet of the Zuyder Zee. The whole territory extends between $49^{\circ}30'$ and $53^{\circ}34'$ N. lat., and $2^{\circ}30'$ and $5^{\circ}58'$ E. long.; making about 280 miles in length, and 220 miles in breadth. The entire extent, according to the best calculations, amounts to 24,870 square miles, or 15,900,000 English acres.

2983. *In respect to surface*, this country includes the lowest portion of the great low land of the European continent. The northern parts, composing the new kingdom of Holland, are mostly below the level to which the bordering sea rises during high tides or swells. Hence originated an imminent danger of inundation, till the Dutch constructed those mighty dikes, by which the sea is excluded, and which form so extraordinary a monument of their industry. Holland is humorously described by Butler as "a country that draws fifty feet of water." The Belgic provinces are also flat, but not lower than the surface of the sea, nor much exposed to river inundation. In the south-eastern district of Liège and Namur, branches of the Rhenish mountains render the surface irregular, and sometimes hilly, particularly in the tract forming part of the ancient forest of Ardennes.

2984. *Several rivers*, which rank among the greatest in Europe, and are derived from distant sources, pass through this territory; and, separating into numerous channels, form broad estuaries at their entrance into the ocean. They all unite in the channel of the majestic Rhine; yet, by a singular fortune, this great name is not retained by the main branch of the river, which, in turning to the westward, receives the name of Waal, and afterwards that of its important tributary the Maese, under which designation it flows into the sea below Rotterdam. The Yssel, another considerable branch, runs northward into the Zuyder Zee; while the name of Rhine is retained by another, comparatively a rivulet, which passes through the provinces of Gueldres and Utrecht. The Maese is the only great river which has the larger part of its course through the Netherlands, traversing the interior of Belgium from south to north. Its main tributaries, the Sambre on the west, and the Roer on the east, have only a portion of their course through Belgium. The Scheldt has not nearly so long a course; but this river, and its tributaries, the Lys, the Dyle, the Dender, and the Neethe, water the most improved districts, and visit the greatest cities of Belgium. When united under their main branch, they form a broad navigable channel, opening into an estuary, which affords to Antwerp the means of carrying on an extensive maritime commerce.

2985. *The only considerable lake in Holland* is Haerlem-Meer, a wide shallow expanse; which, however, was of great service to the Dutch during their grand struggle for independence, by giving them the means of laying the surrounding country under water. There are several smaller lakes of the same character in Friesland.

SECT. II. *Natural Geography.*SUBSECT. 1. *Geology.*

2986. *The higher parts of this country* are composed of *strata of transition slates and quartzes*, more or less inclining to sandstone, generally directed from N. E. to S. W., and traversed by numerous veins of quartz. These slates are *clay slate, whet slate or hone, drawing slate or black chalk*. Resting upon the transition rocks occur various secondary deposits. The first formation is the old *red sandstone*, upon which rests the *mountain limestone*. Associated with these rocks are various slate clays, and beds of *anthracite or glance coal*. Mines of *brown iron ore*, or hydrate of iron, and of *red iron ore*, or oxide of iron, occur among these rocks. A great field of the *coal formation*, resting upon this mountain limestone, extends from Aix la Chapelle to Douay. The coal formation in this tract of country forms a series of irregular basins, of which the most considerable are those of Liège and Charleroi, which are separated from each other by a small ridge of limestone. The chief rocks of these coal-basins are sandstone, slate, clay ironstone, and coal. The most important coal mines are those in the neighbourhood of Mons and Charleroi; but the mines of Liège are remarkable on account of the difficulties the miners meet with in their workings; the number of beds of coal being reckoned as high as eighty-three by M. Dumont. From Aix la Chapelle by Maestricht and Brussels, the country is composed of chalk, with occasional displays of green sand, gault, and Shanklin sand, rising from under it.

2987. *The trutonian* or lower tertiary rocks form in the Netherlands a very considerable basin, in which is situated the city of Brussels. It is composed principally of sands, ferriferous sandstones, white sandstones, flint, limestone, and clayey marl. These tertiary deposits are observed more or less deeply covered with *diluvium*; and at the mouths of the Scheldt, Meuse, and Rhine, there are vast deposits of river *alluvium*, which alluvium forms also the island of Zeeland, and the greater part of Holland.

SUBSECT. 2. Botany.

2988. The *Botany* of this country has been already noticed under that of Germany.

SUBSECT. 3. Zoology.

2989. *The Native Zoology* offers nothing peculiar from that of the adjacent kingdoms. The

DUTCH HORSE.

Dutch horses (*fig. 391.*) are only valuable for draught: those of Friesland, Berg, and the country of Juliers, are the best; but their feet are generally large, they eat much, and have little endurance. The Flemish sheep are of a breed common to France and the Netherlands, being in general hornless, high on the legs, and derived from an intermixture with the Barbary long-legged sheep. The Dutch oxen are of an immense size, Major Smith having seen one which weighed 2000 lbs. This race appears to have been derived from Denmark, and to have produced the Holstein, which was the parent of the old unimproved English breeds.

SECT. III. Historical Geography.

2990. *The Netherlands* formed, in ancient times, the principal part of *Gallia Belgica*. The Belgæ were the rudest, the bravest, and the fiercest of the three nations of Gaul. A desperate struggle was maintained before they yielded to the genius of Cæsar, and the superior discipline of the Roman armies. At length the country within the Rhine was reduced to the condition of a Roman province; but the Batavi, the ancient Hollanders, united themselves to Rome rather as allies than subjects.

2991. *During the middle ages* the Netherlands passed through a series of vicissitudes. So early as the era of Charlemagne, they had acquired distinction in the pursuits of industry; and some of their fabrics were sent by that monarch to the caliph Haroun Alraschid, as specimens of the arts and industry of Europe. When the empire of Charlemagne fell to pieces, these states were divided into a number of separate principalities, all successively united, by marriage contract or inheritances, under the sway of the house of Burgundy. It was at this time that the Flemish provinces rose to the highest pitch of manufacturing and commercial prosperity. They received all the raw materials of France and England, countries then rude and agricultural, and returned them in a manufactured state. Ghent alone is said to have employed 40,000 looms; though this is most probably much exaggerated. Bruges first, and then Antwerp, formed the grand depôt for the commerce of the northern and middle states of Europe.

2992. *The house of Austria*, by the intermarriage of Maximilian I. and Mary, the heiress of Burgundy, succeeded to the rich dowry of the Seventeen Provinces. They formed one of the chief sources of the power of Charles V., who transmitted them, with Spain and his Italian dominions, to his son Philip II.

2993. *The Reformation* was early introduced into the Netherlands, and had a most powerful influence upon their destiny. Being suited to the sober and thinking habits of a manufacturing population, it was soon embraced by a majority of the people, who were thus placed in direct collision with the fierce and gloomy bigotry of Philip II. The Inquisition being introduced, in its most unrelenting severity, with a view to the suppression of the new doctrine, drove the people into open rebellion; and a contest of fifty years' duration arose, the most fierce, bloody, and important in its consequences, of all those to which differences of religion have given rise. The duke of Alva, who boasted that, during his government in the Low Countries, 18,000 persons had perished on the scaffold, was, however, unable to subdue the independent spirit and determined enmity to Spanish dominion which he had been instrumental in kindling. The more moderate conduct of his successors, and, above all, of Alexander Farnese, succeeded in re-establishing the Spanish sway over the Belgic provinces which were not defended by any natural barriers. Even the Dutch were reduced to the disastrous necessity of opening their dikes, and allowing a great part of their territory to be inundated. Their courage and perseverance, however, the great talent of the first two princes of the house of Orange, and the aid afforded by Elizabeth, enabled them

finally to achieve their independence. The union of Utrecht, when they constituted themselves into an independent state, by the title of the Seven United Provinces, was concluded in 1597.

2994. *From this period* the destiny of the United Provinces, called more commonly by the name of Holland, the chief province among them, was entirely different from that of Belgium. They speedily attracted many of the manufactures, and all the commerce, which had raised the Flemish cities to prosperity. The Dutch conquered from Portugal, at that time under the dominion of Spain, the finest of her possessions in the East Indies; obtained a temporary footing in Brazil; and rendered Amsterdam the centre of a flourishing trade with India: they carried on the fisheries, especially those of herrings, upon an unprecedented scale; and became the first maritime people in the world. The commercial greatness of Holland presents so remarkable a phenomenon, that we cannot forbear availing ourselves of some part of that luminous illustration of it, which has been afforded by the researches of Mr. McCulloch. That able writer observes:—

“Between the years 1651 and 1672, when the territories of the republic were invaded by the French, the commerce of Holland seems to have reached its greatest height. De Witt estimates its increase from the treaty with Spain, concluded at Munster in 1643, to 1669, at fully a half. He adds, that, during the war with Holland, Spain lost the greatest part of her naval power; that since the peace, the Dutch had obtained most of the trade to that country, which had been previously carried on by the Hanseatic merchants and the English; that almost all the coasting trade of Spain was carried on by Dutch shipping; that Spain had even been forced to hire Dutch ships to sail to her American possessions; and that so great was the exportation of goods from Holland to Spain, that all the merchandise brought from the Spanish West Indies was not sufficient to make returns for them.

“At this period, indeed, the Dutch engrossed, not by means of any artificial monopoly, but by the greater number of their ships, and their superior skill and economy in all that regarded navigation, almost the whole carrying trade of Europe. The value of the goods exported from France in Dutch bottoms, towards the middle of the fourteenth century, exceeded 40,000,000 livres; and the commerce of England with the Low Countries was, for a very long period, almost entirely carried on in them.

“The business of marine insurance was largely and successfully prosecuted at Amsterdam; and the ordinances published in 1551, 1563, and 1570, contain the most judicious regulations for the settlement of such disputes as might arise in conducting this difficult but highly useful business. It is singular, however, notwithstanding the sagacity of the Dutch, and their desire to strengthen industrious habits, that they should have prohibited insurance upon lives. It was reserved for England to show the advantages that might be derived from this beautiful application of the science of probabilities.

“In 1690, Sir William Petty estimated the shipping of Europe at about 2,000,000 tons, which he supposed to be distributed as follows:—viz. England, 500,000; France, 100,000; Hamburgh, Denmark, Sweden, and Dantzic, 250,000; Spain, Portugal, and Italy, 250,000; that of the Seven United Provinces amounting, according to him, to 900,000 tons, or to nearly one half of the whole tonnage of Europe! No great dependence can, of course, be placed upon these estimates; but the probability is, that, had they been more accurate, the preponderance in favour of Holland would have been greater than it appears to be; for the official returns to the circulars addressed in 1701 by the commissioners of customs to the officers at the different ports, show that the whole mercantile navy of England amounted at that period to only 261,222 tons, carrying 27,196 men. (*Macpherson's Annals of Commerce*, anno 1701.)

“It may, therefore, be fairly concluded, that, during the seventeenth century the foreign commerce and navigation of Holland was greater than that of all Europe besides; and yet the country which was the seat of this vast commerce had no native produce to export, nor even a piece of timber fit for ship-building. All had been the fruit of industry, economy, and a fortunate combination of circumstances.

“Holland owed this vast commerce to a variety of causes: partly to her peculiar situation, the industry and economy of her inhabitants, the comparatively liberal and enlightened system of civil as well as of commercial policy adopted by the republic; and partly also to the wars and disturbances that prevailed in most European countries in the sixteenth and seventeenth centuries, and prevented them from emulating the successful career of the Dutch.

“Many dissertations have been written to account for the decline of the commerce of Holland. But, if we mistake not, its leading causes may be classed under two prominent heads, viz. first, the natural growth of commerce and navigation in other countries; and second, the weight of taxation at home. During the period when the republic rose to great eminence as a commercial state, England, France, and Spain, distracted by civil and religious dissensions, or engrossed wholly by schemes of foreign conquest, were unable to apply their energies to the cultivation of commerce, or to withstand the competition of so industrious a people as the Dutch. They, therefore, were under the necessity of allowing the greater part of their foreign, and even of their coasting trade, to be carried on in Dutch

bottoms, and under the superintendence of Dutch factors. But after the accession of Louis XIV. and the ascendancy of Cromwell had put an end to internal commotions in France and England, the energies of these two great nations began to be directed to pursuits of which the Dutch had hitherto enjoyed almost a monopoly. It was not to be supposed that, when tranquillity and a regular system of government had been established in France and England, their active and enterprising inhabitants would submit to see one of their most valuable branches of industry in the hands of foreigners. The Dutch ceased to be the carriers of Europe, without any fault of their own. Their performance of that function necessarily terminated as soon as other nations became possessed of a mercantile marine, and were able to do for themselves what had previously been done for them by their neighbours.

“ Whatever, therefore, might have been the condition of Holland in other respects, the natural advance of rival nations must inevitably have stripped her of a large portion of the commerce she once possessed. But the progress of decline seems to have been considerably accelerated, or rather, perhaps, the efforts to arrest it were rendered ineffectual, by the extremely heavy taxation to which she was subjected, occasioned by the unavoidable expenses incurred in the revolutionary struggle with Spain, and the subsequent wars with France and England. The necessities of the state led to the imposition of taxes on corn, on flour when it was ground at the mill, and on bread when it came from the oven; on butter, and fish, and fruit; on income and legacies; the sale of houses; and, in short, almost every article either of necessity or convenience. Sir William Temple mentions that in his time — and taxes were greatly increased afterwards — one fish sauce was in common use, which directly paid no fewer than *thirty* different duties of excise; and it was a common saying at Amsterdam, that every dish of fish brought to table was paid for *once* to the fisherman, and *six* times to the state.

“ In consequence principally of the oppressiveness of taxation, but partly, too, of the excessive accumulation of capital that had taken place while the Dutch engrossed the carrying trade of Europe, profits in Holland were reduced towards the middle of the seventeenth century, and have ever since continued extremely low. This circumstance would of itself have sapped the foundations of her commercial greatness. Her capitalists, who could hardly expect to clear more than two or three per cent. of nett profit by any sort of undertaking carried on at home, were tempted to vest their capital in other countries, and to speculate in loans to foreign governments. There are the best reasons for thinking that the Dutch were, until very lately, the largest creditors of any nation in Europe. It is impossible, indeed, to form any accurate estimate of what the sums owing them by foreigners previously to the late French war, or at present, may amount to; but there can be no doubt that at the former period the amount was immense, and that it is still very considerable. M. Demeunier (*Dictionnaire de l'Economie Politique*, tome iii. p. 720.) states the amount of capital lent by the Dutch to foreign governments, exclusive of the large sums lent to France during the American war, at *seventy-three* millions sterling. According to the author of the *Richesse de la Hollande* (ii. p. 292.), the sums lent to France and England only, previously to 1778, amounted to 1,500,000 livres tournois, or sixty millions sterling. And besides these, vast sums were lent to private individuals in foreign countries, both regularly as loans at interest, and in the shape of goods advanced at long credits. So great was the difficulty of finding an advantageous investment for money in Holland, that Sir William Temple mentions, that the payment of any part of the national debt was looked upon by the creditors as an evil of the first magnitude. ‘They receive it,’ says he, ‘with tears, not knowing how to dispose of it to interest with such safety and ease.’

“ Among the subordinate causes which contributed to the decline of Dutch commerce, or which have, at all events, prevented its growth, we may reckon the circumstance of the commerce with India having been subjected to the trammels of monopoly. De Witt expresses his firm conviction, that the abolition of the East India Company would have added very greatly to the trade with the East; and no doubt can now remain in the mind of any one that such would have been the case. The interference of the administration in regulating the mode in which some of the most important branches of industry should be carried on, seems also to have been exceedingly injurious. Every proceeding with respect to the herring fishery, for example, was regulated by the orders of government, carried into effect under the inspection of officers appointed for that purpose. Some of these regulations were exceedingly vexatious. The period when the fishery might begin was fixed at five minutes past twelve o'clock of the night of the 24th of June! and the master and pilot of every vessel leaving Holland for the fishery were obliged to make oath that they would respect the regulation. The species of salt to be made use of in curing different sorts of herrings was also fixed by law; and there were endless regulations with respect to the size of the barrels, the number and thickness of the staves of which they were to be made; the gutting and packing of the herring; the branding of the barrels, &c. &c. (*Histoire des Pêches, &c. dans les Mers du Nord*, tom. i. chap. 24.) These regulations were intended to secure to the Hollanders that superiority which they had early attained in the fishery, and to prevent the

reputation of their herrings from being injured by the bad faith of individuals. But their real effect was precisely the reverse of this. By tying up the fishers to a system of routine, they prevented them from making any improvements; while the facility of counterfeiting the public marks opened a much wider door to fraud, than would have been opened had government wisely declined interfering in the matter.

"In despite, however, of the East India monopoly, and the regulations now described, the commercial policy of Holland has been more liberal than that of any other nation. And in consequence, a country not more extensive than Wales, and naturally not more fertile, conquered, indeed, in a great measure from the sea, has accumulated a population of upwards of two millions; has maintained wars of unexampled duration with the most powerful monarchies; and, besides laying out immense sums in works of utility and ornament at home, has been enabled to lend hundreds of millions to foreigners."

2995. *The French revolution* produced a movement so great, and with which Holland was in such close contact, that it acted powerfully upon her political destinies. The revolutionary armies, after having defeated those of all the allied powers on the plains of Belgium, advanced into Holland; where, meeting with support from a powerful internal party, they had no difficulty in subverting the dynasty of the house of Orange. In its stead was formed the Batavian republic, virtually united to, and ruled by, the republican government of France. A vigorous attempt, made in 1799, by Britain and Russia, to re-establish the old order of things, was baffled; and no sooner had Napoleon been made emperor of France, than he bestowed Holland, formed into a kingdom, on his brother Louis. This prince, of a mild and amiable temper, was disposed to promote the welfare of the Dutch; but he was allowed only to act as viceroy to his brother, and was obliged to assist in forwarding those measures by which Napoleon, in the vain hope of ruining Britain, endeavoured hermetically to seal all the ports of the Continent against foreign commerce. This system was most distressing to all countries subjected to it; but to Holland it was peculiarly ruinous: that maritime commerce on which her whole greatness had rested, received a blow from which, perhaps, it will never recover.

2996. *The kingdom of the Netherlands* grew out of the measures adopted by that great coalition which, after a long series of triumphs, totally overthrew the colossal fabric that had been raised by the genius of Napoleon and the bravery of the French. After its fall, Austria might have advanced a claim to the Netherlands, so long a portion of her extended dominion. Being, however, so remote, and so much detached from her other territories, it was likely to prove a dependency inconvenient and difficult to defend. She therefore consented to accept indemnification in another quarter, and to allow Belgium, with Holland, to be formed into a representative kingdom, under the house of Orange; believing it might serve as a barrier against any future encroachment of France. The kingdom of the Netherlands, thus formed, was divided into two distinct parts, Holland and Belgium; but the latter, differing in religion, language, and manners, was always discontented at this union, and considered itself as a subject state. Inspired by the example of France in 1830, the people rose in arms, and, after a short but desperate struggle, succeeded, with the ultimate consent of the great powers, in forming themselves into a separate kingdom, under the name of Belgium. It comprises the provinces of South Brabant, East and West Flanders, Antwerp, Hainault, Namur, Liège, the greater part of Limburg, and a small part of Luxemburg. Holland, besides the ten United Provinces, has nearly all Luxemburg, and a small part of Limburg, containing, however, Maestricht, its largest town.

SECT. IV. *Political Geography.*

2997. *A limited monarchy*, modelled pretty nearly after that of Britain, was the constitution established for the new kingdom of the Netherlands, and continued in both the parts into which it has been separated.

2998. *The legislative power* is vested in the states-general; a popular assembly, modified, however, somewhat differently from those either of Britain or France. Each province, as under the ancient Dutch system, has an assembly of its own, which regulates local affairs, and has even the power of imposing local taxes. It cannot, however, injure commerce, by imposing heavier duties on the produce of other provinces than its own. The members of these assemblies are chosen by electoral colleges formed in every great town; not by public meeting, or open election; but by the police officers going from house to house, and collecting billets signed and sealed. The members of the second chamber are chosen for three years, one third of the number being annually renewed. The upper chamber does not consist of hereditary nobles, but of a council of from forty to sixty, named by the king for life. The members of the upper house have a salary of 270*l.*, and those of the lower of 220*l.*

2999. *The revenue* of the kingdom of the Netherlands amounted to about 7,500,000*l.*, raised by the usual expedients of land-tax, excise, customs, stamps, post-office, and by a tax on *patents*. These are required to be taken out by all persons exercising trades or professions; and partake of the character of an income tax, inasmuch as their magnitude is determined by the extent of the sales made by the parties during the preceding year.

The article finances means chiefly the interest of the public debt. This amounted, in 1826, to upwards of four per cent. on a capital of 832,334,500 florins. The debt was almost wholly contracted by the Dutch, principally during their protracted and glorious struggle for independence, and partly during the period that Holland was connected with France.

The total annual average expenditure, during the above-mentioned years, was 98,106,820 florins, or about 8,175,568*l.*; exceeding the ordinary revenue by about 800,000*l.* a year.

3002. *The military force of the kingdom of the Netherlands* was in a somewhat large proportion to its resources. This was supposed to be rendered necessary by the proximity of so great a power as France, whose attack, or at least whose dictation, there might be room to apprehend. The army, before the late changes, amounted to about 62,000 men. The Belgic provinces, having been long the principal theatre of hostility between France and Austria, were guarded by a line of strong fortresses. These had been allowed to fall somewhat into decay; but the allies, having brought their contest with France to a triumphant conclusion, determined to strengthen them as a barrier against the future encroachments of that power; and the large contributions levied upon her were, in a great measure, employed in restoring the fortresses to their original condition. Several of these, however, by an agreement made between the French and English governments, have been recently dismantled.

3003. *In naval affairs*, Holland, no longer the maritime rival but the close ally of Britain, made only faint attempts to raise her navy from the low state to which it was reduced by the disasters of the revolutionary war. Its present force does not exceed sixteen ships of the line and ten frigates. Those in active service, in 1829, carried 720 guns, and 4314 men.

3004. *The foreign possessions of Holland*, after being entirely wrested from her during the war, were, with the exception of Ceylon, the Cape of Good Hope, Demerara, and Berbice, restored in 1814. In the East Indies, she possesses the Moluccas, the extensive and fertile island of Java, with settlements on Sumatra, Celebes, and Borneo; and some factories on the coast of Malabar and Coromandel. In Africa, she retains El Mina, and other factories on the Gold Coast. Her West India colonies are not, and never were, very considerable, unless as commercial depôts. Both the navy and the colonial possessions, in the separation of the two kingdoms, remain with Holland.

SECT. V. *Productive Industry.*

3005. *There is no country*, perhaps, which, in proportion to its extent and original resources, produces so great an amount of valuable and useful commodities as Holland and Belgium.

* The expenses of canals, dikes, and navigation in general.

† The charges for education are now included under the head of "interior."

3006. *The agriculture* of the Belgic provinces, though, contrary to the usual course, it was founded upon their manufactures and commerce, being exempted from the vicissitudes which befell them, continues to form the most ample source of wealth. The whole territory of Flanders is cultivated like a garden. A great proportion consisted originally of harsh, barren sands, producing nothing but heath and fir; yet by the application of manure these were gradually reclaimed, and brought into their present state of high fertility. The culture of artificial grasses, and especially of clover, is the characteristic process of Flemish husbandry, which it has taught to the rest of Europe. The care of the Flemish farmers in collecting manure was early conspicuous, and as naturally grew out of the use of artificial grasses, and consequent stall-feeding. The use of liquid manure, collected in large reservoirs, is common to this country with China, and not known in any other part of Europe, except, perhaps, Norway. Turf ashes, especially those imported from Holland, are in high estimation, and are said to produce an almost magical effect on the vegetation of clover. In general, the Flemish agriculture is conducted on a careful, economical, antique practice; the farmers not having adopted many modern improvements in the arrangements of husbandry, such as the crossing of the breeds of cattle, and the use of machinery, which have been adopted in England with such happy effect. But this system of agriculture, after supplying the most dense population in Europe with the standard productions of the soil, yields several articles, such as madder, rape, clover, and mustard seeds, hops, &c., for exportation.

3007. *The objects of culture* in the Dutch provinces, in consequence of their humid climate, and of the demand for animal food for the great cities, are almost entirely connected with pasturage. Holland is as it were one great meadow, intersected by canals, and traversed by rows and groups of trees. The cattle are stalled in the winter, and fed on hay, turnips, &c.; but in summer they are kept constantly grazing in the open air. The produce of the dairy has been brought to such a state of improvement as to be an object of exportation; Dutch butter enjoys a high reputation, and their cheese is in good repute over all Europe.

3008. *Horticulture*, which elsewhere is only a recreation, has in the Netherlands attained such importance, as to become a national object. Besides amply supplying its own markets with culinary vegetables, Holland exports them in large quantities to Norway, and other districts, where the growth is prevented by the rigorous climate. Ornamental gardening has been cultivated with peculiar ardour, especially its floral department. When the tulipomania reigned in Holland, it was carried to such an excess, that lots of 120 tulip-roots sold, in 1637, for 8250*l.*; and particular specimens have brought 733*l.* and 825*l.* In point of fact, however, these roots formed a kind of imaginary currency, or medium for a systematised species of gambling. They were never actually transferred from one individual to another; but, like the shares in our bubble companies in 1825, were a sort of stock whose whole value was derived from caprice. The government at length put down this species of gambling, and the prices of tulips fell to their natural level. — Careful enquiries carried on by the government of the Netherlands, are considered as having proved that the agricultural capital of the whole country amounted to 10,395,000,000 livres, about 433,000,000*l.* sterling. The following estimate was made of the growth and produce: —

	Hectares.		Value in Francs.
Wheat	350,000	-	154,000,000
Rye	700,000	-	168,000,000
Buckwheat	200,000	-	32,000,000
Barley	280,000	-	84,000,000
Pulse	110,000	-	48,000,000
Potatoes	131,000	-	41,000,000
Oats	300,000	-	84,000,000
Orchards	54,000	-	3,000,000
Vegetables	92,000	-	55,000,000
Hemp and flax	210,000	-	126,000,000
Madder	30,000	-	21,000,000
Cattle and animals	-	-	150,000,000
			966,000,000

About 40,250,000*l.* sterling.

3009. *Manufacturing industry* is the branch in which the Belgic provinces formerly most excelled, and in which their decay has been most conspicuous. Three centuries ago, the linens and woollens of Ghent, Louvain, Brussels, and Mechlin clothed the higher ranks in all the surrounding countries. Since that time, the fabrics of France and England have attained such an astonishing superiority, and are at once so cheap, and so well adapted to the taste of the age, that the Low Country manufacturers can with difficulty maintain their ground even in internal consumption. In cottons, especially, they are quite unable to with-

stand British competition. There are still, however, some fine linen fabrics, laces, lawns, cambrics, in which the manufacturers of Mechlin, Brussels, &c. continue unrivalled, and which, though so much superseded by muslin and Nottingham lace, still enjoy a certain demand throughout Europe. The fine laces have been sold for seventy or eighty Napoleons a yard. The Flemish breweries are also very extensive.

3010. *The manufacturing industry of Holland* is not on so great a scale as her commerce. The pottery ware of Delft has lost most of its ancient reputation, and even in Holland is superseded by the earthenware of England. The spirit called gin, geneva, or hollands, is produced at Schiedam, Amsterdam, and other towns, of an excellence which is universally acknowledged. The refining of sugar, and the manufacture of snuff, are continued on a great scale, chiefly in Amsterdam and Rotterdam, and the making of tobacco-pipes at Gouda is said to employ 5000 persons. Silk, leather, woollens, are still manufactured, though not to such an extent as formerly, nor much with a view to exportation. The general value of Dutch and Belgian manufactures has been estimated as follows: —Iron, 46,000,000 francs; copper, 5,000,000; woollens, 80,000,000; linens, 95,000,000; lace, 25,000,000; cottons, 50,000,000; refined sugar, 14,000,000; salt, 10,000,000; spirits, 40,000,000; beer, 110,000,000; tobacco, 28,000,000; oil, 30,000,000; soap, 10,000,000; leather, 28,000,000; earthenware, 4,000,000; bricks, 6,000,000; books, 15,000,000; bleaching, 10,000,000; dyeing, 10,000,000; paper, 8,000,000: in all, 675,000,000 francs, or 28,000,125*l.* sterling.

3011. *The commerce of the Netherlands* has declined, both absolutely and relatively, but in a less remarkable degree. The causes have appeared in the historical survey. The total suspension of all maritime intercourse with other countries during the subjection of Holland to France, and the conquest of the Dutch colonies by England, rendered it necessary, as it were, to begin every thing afresh at the restoration of peace in 1815. But the large capitals in the hands of the Dutch merchants, their commodious situation in the centre of the most improved states of Europe, the recovery of some of the most valuable of their foreign possessions, and the considerable surplus of native commodities which their country affords for exportation, secured for them, as soon as the ports were open, a considerable trade. Since the peace, it has been continually increasing; and, previously to the late revolution, was more equally distributed than before among the Belgic as well as the Dutch ports. Holland exports, of its own produce, butter, cheese, geneva, tobacco-pipes; of the produce of its fishery, herrings, stockfish, whalebone, whale oil; from its foreign possessions, coffee, sugar, rum, cotton wool, cloves, nutmegs, mace, pepper; with linens, wool, and various articles from Germany and the Baltic. Belgium exports madder, vegetable oils, lace, lawn, and fine linen.

3012. *There are no official returns of imports and exports published*; but a very able writer in the *Foreign Quarterly Review*, to whose researches we have been much indebted, has given from original sources the following account of the *importation* of the principal articles of merchandise into the Netherlands ports during the year 1827: —

ARTICLES.	PORTS.			
	Amsterdam.	Rotterdam.	Antwerp.	Middleburg.
Coffee, bales - - -	111,059	97,397	376,102	2,678
Ditto, tons - - -	2,603	1,079	3,539	117
Sugar, chests - - -	12,160	7,508	56,356	
Ditto, mats - - -	2,927	8,145	50,939	79
Ditto, tons - - -	18,653	3,829	4,028	2,609
Tobacco of America, tons	15,205	13,934	1,331	
Rice, bales - - -	1,980	13,892	16,359	
Ditto, tons - - -	8,412	5,301	14,935	
Cotton, bales - - -	12,092	19,907	22,856	152
Indigo, chests - - -	66	476	1,332	
Ditto, syrons - - -	128	88	611	
Tea, quarter chests -	15,124	9,527	1,467	4,200
Skins, pieces - - -	9,271	34,501	215,044	
Pepper, bales - - -	31	5,247	21,847	
Wheat, lasts - - -	12,494	1,602	26	
Rye, ditto - - -	7,835	5,130	96	
Barley, ditto - - -	878	1,412		
Potash of Russia, puds *	50,583	24,791	106,920	
Linseed Oil of Do. do. -	1,246			
Tallow of Ditto do. -	9,416	835	1,191	
Hemp of Ditto do. -	19,110	4,555	8,372	

3013. *The fishery*, which once formed so ample a source of Dutch wealth, (though in this respect its importance has been greatly exaggerated,) was almost annihilated during the war; and the ground having since been occupied by neighbours and rivals, Holland has been able to recover only a small portion. Instead of 1500 herring busses, in 1818 she sent out only 200. Not more than sixty ships go annually to the whale and cod fish-

* A Russian weight of 36 lbs.

eries; and, during the late war, the English undertook the task of supplying their own markets with fresh fish; in which business, however, the Dutch still employ about 6000 boats. The entire produce of the Netherlands fisheries is not reckoned to exceed 1,000,000*l.* sterling.

3014. *For other commercial particulars*, M. de Cloet states, that on an average of twenty years, between 1775 and 1795, the number of vessels entered inwards in all the Dutch ports was 4140, and outwards the same; making a total of 8280 a year. The entries inwards, in 1822, for Amsterdam, Rotterdam, and Antwerp, were 4051; which, adding 500 for Harlingen and Dort, becomes 4551. The numbers outwards for the same three ports were 4045, which we may, with a similar addition, call 4545; making a total of 9096 ships. In 1827, the number entered inwards was 5203, outwards 4548, making 9751 altogether. Taking the average number, however, at 10,000 (instead of 9751), so as to cover the trifling trade of Ostend and Nieuport, and valuing each cargo, with M. de Cloet, at 40,000 francs, a sum moderate enough, the amount of the trade by sea will be 400,000,000 francs. The trade by land with France and Germany, which, in 1814, was estimated at 152,000,000 francs, may now be taken at 160,000,000; so that, if the calculations be at all within the bounds of truth, the annual value of the foreign commerce of the Netherlands is altogether about 560,000,000 francs, or 24,666,666*l.* sterling.

3015. *Mines*. The south-eastern provinces in the neighbourhood of Mons, Charleroi, and Liège, are said to contain 350 mines of coal, employing 20,000 men; but this number we should think, must be a good deal exaggerated. Turf is the fuel chiefly used, especially in Holland. There are also in the southern district ironworks, supposed by Mr. Jacob to yield about 1000 tons. Clay suited for the manufacture of porcelain is found in Holland, and there are stone quarries in the south.

3016. *Canals* form one of the most remarkable features in the economical arrangements of Holland, and a leading source of her prosperity. From the structure of the country, these are formed with peculiar facility, and it is every where intersected with them; every town, every village, being connected by canals of greater or less dimensions. They run through the streets of the cities, enabling vessels to load and unload under the eye of the merchant. When frozen, they serve as highways, on which the Dutch females, heavily laden, convey themselves along on skates with surprising rapidity. In general, from the flatness of the country, and the abundance of water, canals may be made without much exertion of art or skill. There is an exception, however, in the canal of Pansterdam, constructed with the view of draining off the superfluous water of the Rhine, by which a great extent of ground was converted into a marsh. It is two miles long, and 200 feet below the level of the sea, the waters being received into three different sets of sluices. It is considered a masterpiece, and completely answered its object. Another, on a most magnificent scale, connecting Amsterdam with the Helder, was commenced in 1819, and finished in 1825, at an expense of about 750,000*l.* It is 50 miles long, 125 feet wide at the surface, 38 feet wide at the bottom, and 20 feet deep. It is calculated to admit ships of war of 46 guns, and merchantmen of 1000 tons' burden. It was constructed to avoid the troublesome navigation to and from Amsterdam through the Zuyder Zee, and the necessity of lightening large vessels before crossing the Pampus. We understand it has answered the expectations of its projectors.

3017. *The canals in Belgium* are spacious and commodious, connecting all the great cities, though not nearly in equal number, nor uniting every village, as in Holland.

SECT. VI. *Civil and Social State.*

3018. *The population* of the kingdom of the Netherlands, though not comparable, as to absolute amount, with that of any of the great states, is superior to them all in one highly important particular, that the country contains a greater density of population on the same surface than any other in Europe, or perhaps in the world. This, in the Belgic provinces at least, is the more remarkable, as they are inhabited, not by a manufacturing population, drawing subsistence from agricultural countries, but by a population subsisting exclusively on the produce of the land itself. The census of 1816 gave a total population of 5,491,945: 2,476,159 for the northern provinces; 3,249,841 for those of Belgium; and 225,945 for the duchy of Luxemburg. This gives an aggregate average density of about 212 to the square mile; but the rate rises much higher in certain provinces. Throughout Belgium the proportion is 296 to the square mile; in the province of East Flanders, however, it is as high as 560. In the united Netherlands the average density is only 180 per square mile; and in Luxemburg, which has much of a German character, it is as low as 66. The census of 1825 gives a population of 6,013,578; and some further augmentation has taken place since.

3019. *The following details* with respect to the population of the Netherlands are extracted from the publications of M. Quetelet, one of the ablest statistical writers of the Continent.—

Table of the Movement of the Population in Holland and Belgium for Ten Years.

Provinces.	Population.		Births.	Deaths.	Marriages.	Divorces.
	1815.	* 1825.				
Zealand	111,108	129,329	55,331	42,436	10,645	27
Guelders	264,097	284,363	90,862	59,818	19,337	13
North Brabant	294,087	326,617	100,863	69,507	20,380	1
North Holland	375,257	393,916	145,744	121,725	34,789	209
South Holland	388,505	438,202	165,741	143,850	34,942	148
Utrecht	107,947	117,405	41,038	29,928	8,982	30
Friesland	176,554	202,530	65,565	38,219	15,327	46
Overijssel	147,229	160,937	51,951	37,479	11,629	13
Gröningen	135,642	156,045	51,673	30,539	11,492	37
Drenthe	46,459	53,368	16,723	9,858	3,954	3
Limburg	287,613	321,246	101,781	70,549	22,960	5
Liège	358,185	331,101	113,623	82,698	24,387	24
Namur	164,400	189,393	58,690	34,134	12,592	8
Luxemburg	213,597	292,610	92,242	58,695	18,740	1
Hainault	488,595	546,190	183,198	118,289	39,591	27
South Brabant	441,649	495,455	169,181	119,109	36,423	5
East Flanders	615,689	687,267	218,830	162,834	43,120	0
West Flanders	516,324	563,826	191,139	141,310	37,882	6
Antwerp	291,565	323,678	101,471	70,623	23,075	2
	5,424,502	6,013,478	2,015,646	1,421,600	430,247	605

3020. The births and marriages in the Netherlands are proportionally more numerous, while the deaths are about equal to those of France, and exceed those of Great Britain in the ratio of three to two. The account stands thus :—

	Netherlands.	France.	Great Britain.
100 births to	2,807 inhabitants	3,168	3,534
100 deaths	3,981	4,000	5,780
100 marriages	13,150	13,490	13,333
100 marriages	468	426	359

There has been a very material increase in the healthiness of the people of the Netherlands, and particularly of Holland, during the last thirty or forty years.

3021. The provision for the support of the poor in the Netherlands is pretty ample, and it is applied with great economy and skill; forming, indeed, an important branch of the public administration. The following table, compiled from authentic sources, by M. Quetelet, cannot fail of being interesting :—

Charitable Institutions of the Netherlands.

Nature of Institution.	Number of Institutions.	Individuals relieved.	Expenses of Relief.	Expense for each Individual.
			Florins.	Florins.
Administrations for relieving the Poor at home	5,129	745,652	5,448,740	7.31
Commissions for distributing Food, &c.	36	22,056	82,424	3.73
Societies of Maternal Charity	4	1,448	13,493	9.32
Hospitals	724	41,172	4,091,157	99.37
Funds for Military Service	1	2,277	110,942	48.73
Royal Hospital of Messine*	1	156	23,290	149.30
Poor Schools	285	147,296	247,176	1.67

Societies of Beneficence for the Colonies	2	8,553	353,529	41.33
Establishments for the Deaf and Dumb	4	239	41,994	175.70
Totals	6,228	977,616	11,049,036	Average 11.30
Monts de Piété	124	-	4,208,068	—
Savings Banks	50	18,035	2,771,608	Average 153.93

3022. The national character of the Dutch has been long moulded into the form natural to a highly commercial people; solid, steady, quiet, laborious, eagerly intent on the accumulation of wealth, which they seek rather by economy, steadiness, and perseverance, than by speculation. They carry the virtue of cleanliness to an extreme. Outward decorum of manners, at least, is better observed than among the neighbouring continental nations. Yet the *spiel* houses in the great towns, where the most respectable citizens used to mingle with persons entirely destitute of character, presented in this respect a strange anomaly. But at present these can hardly be said to exist; and are frequented only by the very dregs of the populace. A traveller in Holland will rarely meet with a drunken person; or with a man, woman, or child, in rags. Every class of people seems comfortable, the result of their great

* In West Flanders, for the daughters of soldiers invalided or killed in service.

frugality and unwearied industry. Were a young sturdy beggar discovered teasing passengers for alms, he would instantly be sent to the workhouse ; where, if he refused to perform his allotted task, he would be compelled to save himself from drowning by working at the pump ! Holland is, and always has been, a country of short credit. Bankruptcy is rarer in it than any where else. Notwithstanding the invasion of the French in 1795, and the consequent interruption to all sorts of business, the bankruptcies were not comparatively so numerous as in England in ordinary years. (*M'Culloch's Com. Dict.*, art. *Amsterdam*.) The Belgic provinces, long subjected to a foreign yoke, and in constant intercourse with foreigners, seem to have lost in a great measure the original Flemish character, and to present no very distinctive features.

3023. *It is not very easy*, from the differences of their judicial organisation, to compare the state of crime in different countries. In this respect, however, the Netherlands would have nothing to fear from a comparison with France and England. In Holland, the police is excellent, and robberies very rare.

3024. *The prevailing religion* of Holland is Calvinism, while that of Belgium is almost exclusively Catholic ; a difference which contributed not a little to that rooted dislike entertained by the inhabitants of the latter to those of the former. The Dutch have the honour of being the first people who established a system of unrestrained toleration. Even popery, notwithstanding the grounds which the nation had to dread and hate it, was allowed to be professed with the utmost freedom. The French government carried liberality a step farther, by allowing salaries, of a greater or less amount, to the clergy of every persuasion, only making those of the Presbyterian ministers higher than the others. The latter retain, besides, the old parish churches, and the exclusive privilege of using bells. They amount to about 1600, and are all paid and appointed by government, which, however, respects the wishes of the leading parishioners. Their salaries are very moderate, 250*l.* in the great cities ; 60*l.* or 70*l.*, with house and glebe, in the country. They are divided, as in Scotland, into moderate and high Calvinistic parties ; the former, which are said to be the most numerous, having the command of the university of Utrecht, while that of Leyden is attached to the opposite interest. There are about 300 or 400 catholic congregations, in general very small. The Arminians, who originated in Holland, have only about forty or fifty ministers ; but their tenets are preached in many of the presbyterian churches. The anabaptists, called here Mennonists, have about 100 congregations, composed of many opulent and respectable members. The Lutherans have fifty or sixty churches ; and the French protestants about thirty.

3025. *In Belgium*, the catholic clergy have shown a very rooted spirit of intolerance, with the bishop of Ghent at their head, and vehemently objected to the indulgent treatment of the other sects. The bishop was imprisoned for two years by Napoleon, on account of his obstinacy in this particular. The great possessions of the church, however, have been forfeited, and the clergy receive very moderate salaries from government. The monasteries have been rooted out, and generally also the nunneries, though that of Ghent still retains all its pomp.

3026. *Learning in the Netherlands* no longer boasts such names as Erasmus, Grotius, and Boerhaave ; but the institutions for its diffusion continue to be very ample. Holland retains its two famous universities of Leyden and Utrecht. The former, which, under Boerhaave, had once the reputation of the first medical school in Europe, is still highly respectable, though attended only by about 300 students. The professors, who are twenty-one in number, receive salaries of 255*l.*, independent of fees ; and this being a better income than any of the ecclesiastical livings, the university draws from the church its most learned members. The professors are still considered the most eminent medical men in Holland ; and while other physicians receive only a fee of 20*s.*, they are paid 10*l.* or 12*l.* The medical education, however, cannot be completed unless at Amsterdam, which affords the advantage of hospitals and other accommodations peculiar to a large city. The university of Utrecht is not so considerable as that of Leyden ; and that of Gröningen is still inferior. In 1827, the number of students was, in Leyden, 588 ; in Utrecht, 498 ; in Gröningen, 287.

3027. *The universities of Belgium*, of which the most celebrated were Ghent and Louvain, were partially stripped of their ample endowments, first by Joseph II., and then by the French, who in their room substituted lyceums, which are now continued nearly on the same footing, under the name of colleges. Only the languages, and some general branches, are taught ; education for professional purposes being received in separate appropriate seminaries. Ghent and Brussels have the highest reputation ; but the salary of professors in the former does not exceed 60*l.* The three universities of Louvain, Liège, and Ghent, have lately been restored ; and in 1827 the first was attended by 678 students ; the second by 506 ; and the third by 404 students. Besides athenæums, which are only colleges on a smaller scale, Holland has primary schools in every village, by which the benefits of education are communicated to the lowest ranks. Belgium is at present very deficient in institutions for popular education. But at an average of the Netherlands,

the proportion of children at school to the entire population, in 1827, was as high as 1 to 9·5; a proportion not exceeded in any European country, with the exception, perhaps, of Prussia.

3028. *The fine arts* were cultivated with zeal and success in both parts of the Netherlands. Wealthy merchants liberally patronised the arts of design; and the gentry and landholders being induced by the constant wars, of which the Low Countries were the theatre, to live much in towns, acquired more refined tastes than could have been formed in a country residence. Antwerp, during its prosperity, became, in some measure, a Belgic Athens. Yet the Flemish and Dutch painters never attained that grandeur of design, and that pure and classic taste, which was formed in Italy, by the study of the antique, and the refined taste of its nobles. The Flemish school, under its great masters Rubens and Vandyke, displayed, however, many excellences in a degree not inferior to any other in modern times; splendour of colouring, grandeur of composition, and force of expression. The Dutch school has been eminently successful in a lower sphere. Under Rembrandt and his disciples, subjects of common life and vulgar humour were treated with a native force, which, being aided by brilliant effects of light and shade, have rendered this school exceedingly popular, though it has failed in all attempts at high and heroic delineation. The landscape painters have seldom employed their pencils upon the grand scenery delineated by Claude and Poussin; but Berghem, Cuyp, Ruysdael, Hobbima, Vandevelde, and others, have represented, in the most natural and pleasing colours, the pastoral scenery of their country; its meadows, its woods, and the banks of its seas and rivers.

3029. *Amusement* is far from being a primary object with the Dutch. They have most of the diversions of the neighbouring nations, though they do not follow them with much ardour. A great portion of their time is passed in smoking; the Dutchman having seldom the pipe out of his mouth. The rivers and canals passing through the streets, afford the opportunity of fishing from the windows.

3030. *The great Flemish kermes, or fairs*, though no longer subservient to commerce, exist still as festivals, at which there is a great display of humour and character, such as we find happily illustrated in the works of the Flemish painters. There seems nothing peculiar in the Dutch style of cookery. The peasantry both of Holland and Flanders have their peculiar local costume; as the huge breeches of the men, and the short jacket of the females; but the higher classes dress in the French or German style.

SECT. VII. Local Geography.

3031. *The following*, according to recent official statements, is the extent and population of Belgium and Holland, respectively:—

BELGIUM.				
Provinces.	Extent in hectares.	Population in Dec. 1827.	Principal Towns.	
South Brabant	328,000	499,728	Brussels - - 72,800	Louvain - - 18,580
Antwerp - -	283,000	338,294	Antwerp - - 65,000	Mechlin - - 16,000
East Flanders -	282,000	708,705	Ghent - - 81,941	St. Nicholas - 10,980
West Flanders	316,000	575,807	Bruges - - 36,000	Ostend - - 10,500
Hainault - -	372,000	567,300	Mons - - 18,400	Ypres - - 15,150
Namur - -	347,000	194,845	Namur - - 15,100	Verviers - - 10,070
Liège - -	288,000	347,625	Liège - - 45,300	Spa - - 3000
Limburg - -	460,000	328,234	Tongres - - 4000	
	2,676,000	3,560,538

3032. *South Brabant*, which nearly coincides with what was formerly the Austrian part of that large province, forms a rich plain in the heart of Belgium and is the seat of the finest manufactures carried on in that country.

3033. *Brussels* (*fig. 392.*) is the capital of Belgium. Considered as such, it is small, yet it is one of the gayest and most elegant cities of Europe. Its situation is fine, in a valley watered by the Senne and the canal to Antwerp. The Allée Verte, consisting of three rows of trees bordering the canal, makes a beautiful approach. The market-place and the park are the two great ornaments of Brussels. The former is of great extent, and surrounded by the town hall, one of the most elegant

BRUSSELS.

Gothic structures in Europe, adorned with a tower, 348 feet high, and by the old halls of the different corporations. The park forms an extensive range of pleasure ground, interspersed with rows of lofty trees, and pleasing lawns, ornamented with fountains and statues; and it is surrounded by all the most spacious and sumptuous edifices. The church and chapel of St. Gudule are also distinguished for the elegance of their ornaments. Brussels has an academy of painting, attended by 400 or 500 students; and in the palace there is a library of 12,000 volumes, and a small but valuable collection of paintings.

3034. *Another ancient and important city* is Malines, or Mechlin (now in the province of Antwerp), still retaining traces of the prosperity derived from the lace bearing its name, which is considered the strongest, though not the finest, made in the Netherlands. Another branch of industry consists in the making of excellent brown beer. The houses are ancient, and very spacious, often constructed in a curious and grotesque manner, and most nicely white-washed. The tower of the cathedral is highly finished, and rises to the height of 348 feet. The other churches contain many of the masterpieces of Rubens and Vandyke. Louvain is equally fallen from the period when its extensive cloth manufactures and its university, one of the first in Europe, gave it a population of 150,000. It is a large ill-built town, whose bulky walls, seven miles in circumference, are now falling to decay. Its catholic university, an attendance on which was once required as a qualification for holding any office under the Austrian government, perished in the French revolution, and was replaced by what could only be called a lyceum; but the ancient institution has since been restored. The town hall, enriched by numerous carved figures, and the collegiate church, whose spire, before its fall, at the beginning of the seventeenth century, rose to the height of 500 feet, are the chief ornament of Louvain.

3035. *Antwerp* (*fig. 393.*), formerly the port of Brabant, has now a province, to which it gives its name. This territory is situated along the Lower Scheldt, and is covered to a

ANTWERP

great extent with pleasure-grounds and houses, erected by the rich merchants during the period when Antwerp was in its glory. That city, down to the close of the fifteenth century, was almost without a rival among the commercial states of Europe. In the great struggle which then arose, Antwerp embraced with ardour the reformed cause, in support

of which it suffered the most dreadful calamities. In 1576 it was sacked by the Spaniards; and being afterwards wrested from them, surrendered on favourable terms, after being besieged for more than a year, to the Prince of Parma. Subjected to the bigoted and tyrannic sway of Spain, and oppressed by the active rivalry of Holland, it lost all its commerce, and presented the mere shadow of its former greatness. Its renewed prosperity dates from its occupation by the French. Bonaparte made it one of his grand naval arsenals, and erected immense works, in the vain hope of creating a fleet which might rival that of Great Britain. Since the peace, Antwerp, having been placed on an equal footing with the ports of Holland, has availed itself of the advantages of its situation, and regained a considerable commerce. Having a ready navigation into the interior, and communicating by canals

with the principal seats of manufacture, it is destined by nature to be the chief emporium of Belgium. In 1825 there entered its port 800 vessels, of which 291 were British. In 1828 the number had increased to 955. Antwerp is still a noble city, containing numerous stately buildings, both private and public, which include some of the finest specimens of Gothic architecture existing. The cathedral, which occupied 100 years in building, is celebrated over Europe. It is 500 feet long, 230 wide, and 360 high. The spire is 466 feet high, of extreme beauty, and from its summit is obtained a magnificent view of the windings of the Scheldt, with the distant towers of Ghent, Malines, and Breda. The interior is adorned with the greatest masterpieces of Rubens and Vandyke, which, after being carried off to Paris, have been again restored. Numerous fine specimens of the Flemish school are found in the other churches, as well as in private mansions. Antwerp has always been the centre of Flemish art; the birth-place of Rubens, Vandyke, Jordaens, Teniers, and all its greatest masters. Zealous patronage is still bestowed upon the art; an academy is supported, at which 400 or 500 students are almost gratuitously taught; annual prizes are given, and crowns placed on the heads of the successful candidates. This encouragement has called forth some respectable talents, though none, as yet, to rival the fame of the old masters.

3036. *East Flanders* is chiefly an inland district, and is the part of Belgium in which culture has been carried to the highest perfection. It displays an aspect of uniform luxuriant fertility, resulting altogether from the application of art and capital. Even in journeying along the road, the traveller finds the wheels of his carriage sinking in the sand, while beyond the hedge on each side, the soil consists of the richest black mould. The most fertile district is called the Waes, or St. Nicholas.

3037. *Ghent*, even in its fallen state, is still one of the noblest of the old cities of Europe. That vast circuit of walls which, according to the boast of Charles V., could contain all Paris within them, may still be traced. It is built on twenty-seven islands, most of them bordered by magnificent quays, and connected by three hundred bridges. The streets, with a few exceptions, are spacious and handsome, and there are many fine old churches; but the great cathedral does not display the architectural grandeur of that of Antwerp, though the interior is rich in the extreme, adorned with numerous pillars of white marble. This and the other churches, as well as the academy, contain numerous paintings by the old Flemish masters. Ghent, though it can no longer send its 40,000 weavers into the field, is still one of the most manufacturing cities of Belgium. Prior to the revolution, its staple was sorted lace; but since the great improvements in the cotton manufacture, several large fabrics have been established at Ghent. The society is good, this being a favourite residence of the old Flemish nobles, and now frequented by a considerable number of English families.

3038. *The other towns in East Flanders* are Dendermonde, a small but strong place, which has stood repeated sieges; Alost, on the eastern frontier; St. Nicholas and Tokerm, two large villages, of more than 11,000 inhabitants each, in the centre of the Waes, flourishing by means of corn markets and of some considerable manufactures. Sas-van-Ghent is the centre of the sluices on the canal to the Scheldt, by which the whole country can be laid under water. Hulst is a strongly fortified little town.

3039. *West Flanders* is a continuation of the same richly cultivated plain which has now been described; yet, being partly mixed with sand and marsh, and exposed to the blighting influence of fogs and sea breezes, it does not display altogether the luxuriant aspect of the Pays de Waes. It has no place comparable to Ghent, yet it comprises an extraordinary number of ancient cities, which still retain a portion of their former prosperity.

3040. *Bruges*, formerly the residence of the counts of Flanders, and one of the factories of the Hanseatic league, was the greatest commercial city in the Low Countries, and perhaps in the north of Europe, till it was first surpassed by Antwerp, and then, from the same causes, shared its fall. Its situation in the midst of so fertile a country, and its communications by spacious canals with the sea and with the interior, still secure to it a considerable trade. Bruges has the character of an old town, the streets being narrow, and the houses lofty. The town hall is its most conspicuous edifice, and it is adorned also with many noble churches, containing some of the finest works of the great Flemish painters. The invention of painting in oil has been ascribed to this city.

3041. *Ostend* is an ancient town, early celebrated for its fortifications. The siege by Spinola, which began in 1601, and lasted two years, was one of the most memorable in modern history; and upon its issue the destiny of the Low Countries was considered to depend. But though it ultimately fell, the exhaustion of the Spanish army, and the time which had been afforded to Holland for collecting her energies, prevented its capture from having the ruinous effects that were anticipated. Under Austrian sway, Ostend, which has one of the few good harbours in Flanders, became the chief theatre of the limited trade of the Belgic provinces. Napoleon restored its fortifications, which were still farther strengthened by the allies. It has not now above a third of its former population, but still carries on a brisk intercourse with England, and has almost the appearance of an English town. In 1828, 574 vessels entered its port.

3042. *Other large fortified places*, celebrated in the military annals of Europe, are found in West Flanders. Courtray, Ypres, and Menin have the usual character of Flemish towns. They are large, rather well built, with handsome churches and town halls; fallen from their ancient prosperity, yet retaining considerable manufactures of linen and beer; and having in the long course of the Low Country wars been repeatedly taken and retaken. Courtray is noted for the very fine flax grown in its neighbourhood. Oudenarde, the scene of one of Marlborough's victories; Dixmuyde, and Furnes, present the same characters on a smaller scale. Nieuport is rather a noted fishing and trading town, surrounded by sluices, by means of which the neighbouring country can be inundated. Lisle and Dunkirk have been finally included by France within her boundaries.

3043. *Hainault*, to the west of Flanders and the south of Brussels, presents a long range of military frontier to the once hostile frontier of France. It is watered by the upper courses of the Scheldt and the Sambre; and, instead of presenting the same dead level with Flanders, is varied by gentle undulations, still highly cultivated, yet not with the same extreme care or ample expenditure. In this province are rich mines of coal, a mineral not found in any other part of the Low Countries; and though Hainault never formed any of the great seats of manufacture, it is by no means deficient in this branch of industry.

3044. *Mons, Tournay, and Charleroi* are the chief towns of Hainault. The description given of the secondary cities of Flanders may apply to them. Mons, called once Hannonia, is very ancient; it is well built, but appears often almost buried under the smoke of the steam-engines employed in working the neighbouring coal mines. It has a very extensive foundling hospital. Tournay, a fine, large, old city, with a handsome cathedral, has stood many sieges. Charleroi, besides its military reputation, has that of making very fine nails, with which it supplies all Belgium. In front of Mons is Genappe, and eight miles east of Charleroi is Fleurus, both celebrated for signal victories gained by the French during the revolutionary war. The large and strong cities of Condé and Valenciennes are now annexed to France.

3045. *Namur*, to the east of Hainault, presents a striking variety from the tame and flat surface which covers the greater part of the Low Countries. Consisting of the valley of the Meuse, which traverses the whole province from north to south, it contains numerous rugged eminences, which give to it a varied and picturesque character. The banks of the river, from Namur to Liège, overhung by wooded rocks, and opening into deep valleys, abound in the most romantic scenes.

3046. *Among the cities*, *Namur* is one of the most ancient in the Low Countries, its origin being traced to the time of the ancient Germans. It lies in a beautiful valley bordered by high mountains, at the confluence of the Sambre and Meuse. The castle, on a high rock, was formerly considered almost impregnable, and stood many sieges, till Joseph II. dismantled, and the French afterwards almost entirely demolished it. The cathedral and the Jesuits' church are fine edifices, and, unlike the other churches of the Low Countries, of Grecian architecture. Namur has in its neighbourhood extensive iron mines, which employ many of the inhabitants; the manufactures of the city consist in working up this metal into fire-arms, cutlery, &c. Ascending the Meuse towards the French frontier, we come to the small fortified towns of Dinant and Charlemont.

3047. *The provinces of Liège and Limburg*, which are much intermingled with each other, form the eastern frontier of Belgium. They run from north to south along the Meuse, fronting Germany, and are, indeed, half German. On the banks of the Meuse, and in some particular districts, the territory is broken and rocky; but most of it consists of an extended and highly cultivated plain. The eastern district is distinguished by the peculiar richness of its pastures, which produce butter and cheese of great value. Its manufactures, also, especially those of fine woollens, are very flourishing.

3048. *Of the cities* in these two provinces, Liège, once the seat of a sovereign bishop, is ancient and large, but upon the whole ill built and gloomy; and though some of its buildings are large, they do not display the taste conspicuous in other Belgic cities. The church of St. Paul is, however, admired, as was that of St. Lambert, till it was destroyed during the revolution. Liège has a manufacture of fine woollen cloths, which sell at a high price. The town of Limburg, now included in Liège, has lost much of its population and industry; and a great part of its precincts is in ruins. Spa, situated amid romantic rocks, is one of the most celebrated watering places in Europe. The resort, though much diminished, is still considerable, and composed of persons of distinguished rank. The inhabitants work the beechwood, which grows in the neighbourhood, into a variety of toys, for which they find a ready sale among the visitors. St. Tron and Tongres are ancient towns, the former having a celebrated Benedictine abbey. Eupen, like Verviers, has flourishing manufactures of cloth. Hervé is the chief market for the Limburg cheese, which goes by its name.

3049. *THE KINGDOM OF HOLLAND*, or, as it was termed under the former régime, the *United Provinces*, now claims our attention.

3050. *The province of Holland* is of paramount importance, including all the great cities

and principal seats of commerce; so that its name was most usually given to the whole republic. It forms a long narrow stripe, almost every where enclosed and penetrated by water; on one side it is washed by the North Sea; on the other, by the Zuyder Zee; in its centre it has the large lake called Haarlem-Meer; while the Rhine and the Lech intersect its numerous channels. The whole country is so low, that it is habitable only by means of enormous dikes, which exclude the sea: when these give way, the waters rush in, and inundate the whole territory. The country forms, in fact, one vast well-watered meadow scarcely any where subjected to the plough, though extensive gardens are cultivated, both for use and ornament. But the chief products are cattle, butter, and cheese, for the supply of the population of the cities, and for export.

3051. *Amsterdam* (*fig. 394.*), the capital of the province and kingdom of Holland, is situated at the point of confluence of the river Amstel with the Y, an arm of the Zuyder

Zee, in lat. $52^{\circ} 25' N.$, long. $4^{\circ} 40' E.$ It was a considerable town in the fourteenth century; but it was not till the sixteenth century, when the persecutions of the Spaniards in Belgium proved fatal to the trade and navigation of Antwerp and the southern provinces, that Amsterdam at-

AMSTERDAM.

tained to the distinction which she enjoyed till about the middle of last century, of being the first commercial city of Europe. It is but justice, however, to state, that her extraordinary progress depended as much, or more, on the liberal and enlightened policy of her rulers, as on external events. Every individual, whatever might be his country or his religion, was received with open arms at Amsterdam; and acquired, by means of a trifling payment, the right of citizenship, and the enjoyment of all the privileges of a native. All the public institutions were calculated to promote commerce; and at a time when trade and industry in other countries were oppressed by prohibitions, in Holland they were comparatively free. When most prosperous, Amsterdam is supposed to have contained about 240,000 inhabitants; but at present the population is not supposed to exceed 200,000. Being built in a marsh, the foundations of the city are laid on piles; and it is a common complaint that a house costs as much below as above ground. The three principal streets are parallel to each other, and are not easily to be matched for length, breadth, and the magnificence of the houses; many of which, though antique, are splendid, and are kept in the best possible repair. The city is intersected by an immense number of canals, communicating by drawbridges, and having sluices for the purpose of regulating the level of the water: these canals are for the most part bordered by fine trees. The expenses incurred in keeping the sluices in order, and in clearing the canals and port of mud, are very heavy. The matchless industry and perseverance of this wonderful people is in nothing so signally displayed as in their works and contrivances for conquering the difficulties incident to their situation, and making the waters, which threaten to overwhelm them, contribute to their comfort. The

STADT-HOUSE, AMSTERDAM.

stadt-house (*fig. 395.*), now the royal palace, is the finest building in the city; and is, indeed, one of the noblest any where to be met with: it is of large dimensions, and is adorned with pillars, and with sculptures emblematical of commerce and navigation. Above 13,000 piles are said to have been employed in forming its foundation. The harbour is inconvenient, large ships being obliged to lighten before they can pass the Pampus or bar at the

mouth of the Y, and the navigation of the Zuyder Zee is also difficult. To remedy these inconveniences, the large canal to the Helder, already alluded to, has been constructed. The trade of Amsterdam has increased considerably within the last few years; and about 2200 ships now annually clear out for foreign countries. None of the water from the canals is made use of for culinary purposes; the town being supplied with fresh water, conveyed in carts from the Vecht, about five or six miles distant; but most of the houses have cisterns, where the

rain-water is collected. There is a national museum of pictures, which contains many fine specimens of the Dutch school. The various prisons and houses of correction and industry at Amsterdam are said to be managed on more approved principles than similar institutions in most parts of Europe. The police is excellent; crimes rare; and no beggars to be seen in the streets. The inhabitants seem vigorous and healthy; but the mortality, though materially diminished within the last thirty or forty years, is still greater than in most European cities; a consequence, probably, of the humidity of the climate, and of the effluvia arising, in summer, from the canals.

3052. *Rotterdam* (*fig. 396.*), the second city in Holland, is more conveniently situated for commerce than

ROTTERDAM.

Amsterdam, having a readier access to the sea; and the Maese, on which it is situated, being so very deep as to admit vessels of the largest draught of water to lie close to the quays. Its commerce is rapidly increasing. Its principal exports are geneva and madder; and it carries on the business of sugar-refining on a large scale. It has all the characteristics of a Dutch town; being neat, clean, uniform; the houses high, and built of

very small bricks. The canals intersecting it are numerous, deep, and, unless in a few of the most crowded streets, connected by draw-bridges. Rotterdam boasts of being the birth-place of Erasmus; to perpetuate whose memory she has erected a handsome statue (*fig. 397.*).

397

STATUE OF ERASMUS.

3053. *Other large and important cities* are included within the limits of the province of Holland.

3054. *The Hague* (*fig. 398.*), though ranking only as a village, is, in fact, one of the handsomest cities in Europe. The streets and squares are well built, bordered with fine walks and avenues of trees. Neither the old nor the new palace can boast of any splendid architecture; but the former is large, and contains some valuable collections. An avenue of two miles leads to the neat fishing town of Scheveling, whence the dealers are daily seen bringing their commodities in little carts drawn by large dogs. Leyden (*fig. 399.*) is a fine old city, situated in the heart of the Rhineland, where this ancient bed of the river is cut into an infinity of canals, which render this the richest meadow land of Holland. The beer, the butter, and the bread of this district are

held in the highest estimation. Leyden, during the war with Spain, was the most important city in Holland, and on the event of its siege the fate of that country was supposed to depend. The Spaniards,

398

THE HAGUE.

by a lengthened and strict blockade, reduced it to the last extremity; while the Dutch could muster no force adequate to its relief. It was then that they formed the magnanimous resolution of breaking down their dikes, and admitting the ocean. It was some time before the full effect was produced; but at

length, impelled by a violent wind, the sea rushed in, overwhelmed all the works of the besiegers, and forced them to a precipitate flight. The little fleet of boats, which had been prepared for the relief of Leyden, immediately sailed over the newly formed expanse, and triumphantly entered the city. The Prince of Orange offered to Leyden the option of two benefits, — an immunity from taxes for a certain period, or the foundation of a university in the city. The citizens crowned their former glory by choosing the latter alternative, and a university was accordingly founded, which speedily became one of the most eminent schools in Europe; and, though much injured by the numerous rivals which have since sprung up, it continues to maintain a high reputation, particularly

as a classical school. Leyden is still a handsome and flourishing town; carries on the woollen manufacture with success, though on a diminished scale; and is a great market for

LEYDEN.

butter and cheese. Haarlem (*fig. 400.*) is another city of ancient importance. In the great struggle for independence, it stood a memorable siege of seven months; when it surrendered upon honourable terms, which were basely violated by the Duke of Alva. Haarlem is still spacious and flourishing, and excels peculiarly in the bleaching of linen and cambric, which it performs for all the neighbouring provinces. The matchless and brilliant white-

HAARLEM.

ness of the Haarem linens has been imputed to a peculiar quality in the water, but is more probably the result of the extreme skill of the inhabitants. acquired by long practice. Flowers are principally raised for sale in the vicinity of Haarlem. Delft, an ancient gloomy town, was formerly celebrated for the manufacture of the ware which bears its name; but this, as already observed, has been almost entirely supplanted by English

earthenware. Dort, or Dordrecht, enclosed by branches of the Maese, was the ancient capital of Holland, while the main commerce of that country continued to centre in this its most natural quarter. It still retains very considerable traces of this early importance. The town-hall and great church are magnificent structures. There is a considerable trade in goods coming down the Rhine, particularly floats of timber, so large that one of them has been valued at 30,000*l.* Gouda is a large flourishing village, in a rich country, and carries on an extensive manufactory of tobacco-pipes. It is celebrated for the excellence of its cheese.

3055. *North Holland* forms a considerable peninsula, almost entirely encircled by the Zuyder Zee and the North Sea, and bordered by sand-hills of some elevation; but the interior is covered with rich pastures, on which are fed large herds of cattle. The ancient and not ungraceful costumes (*fig. 401.*) of the Dutch peasantry are preserved with greater exactness in this sequestered part of Holland, than in any other; and the fishery, for which their situation is peculiarly adapted, is carried on with great activity. Alkmaar is an agreeable

PEASANTRY OF HOLLAND.

town, with a great traffic in butter and cheese, and a manufacture of nets. The most important places in North Holland are the Helder and the Texel, two grand naval stations; the one a strong fort, commanding the entrance of the Zuyder Zee; the other an island opposite, in which the Dutch fleets used to rendezvous, from the facility it afforded for their getting to sea. Along the coast of the Zuyder Zee are the considerable

towns of Hoorn and Enkhuysen, and the smaller ones of Edam and Purmerende.

3056. *Zealand* is a region more completely enclosed by, and sunk below, the level of the water, than any other part of the United Provinces. It consists of nine islands, formed and environed by branches of the Maese and the Scheldt, as, passing from the state of rivers into friths, they unite with the ocean. The mariner, in approaching, sees only points of the spires peeping above the immense dikes which defend them from inundation. The soil is moist and rich, peculiarly adapted to the cultivation of madder. The damp air, however, and the exhalations from the waters, render these islands unhealthy, and even fatal to foreigners,

as was too dreadfully experienced by our troops while quartered at Walcheren; but the natives do not experience the same pernicious effects. Middleburg is a considerable city, with a town-hall and several churches, which afford fine specimens of Gothic architecture. Flushing, with its attendant town of Ulyssingen, is an eminent naval station, and has a considerable trade and fishery. The island of Schowen has Zieriksee, the ancient capital of the counts of Zealand; and South Beveland has Goes, or Tergoes, with a considerable trade in salt.

3057. *Utrecht*, a more inland province than Holland, forms a continuation of the same tract of flat meadow land, interspersed with gardens and country residences. Utrecht, the capital, is a remarkably agreeable city, and being a little elevated, the view from its ramparts and the top of its cathedral over the vast plains and broad waters of Holland is extensive and delightful. The Romans called it *Ulpia Trajectum*, as commanding an important passage over the Rhine; and in the middle ages it was held by the warlike bishops of Utrecht. In this city was concluded the treaty of confederation, in 1597, by which the United Provinces were constituted, and also the celebrated treaty of 1715, which terminated the long war of the Spanish succession. Amersfort, pleasantly situated on the Ems, and noted as the birthplace of Barneveldt, has considerable fabrics of dimity and bombazeen, and extensive bleaching grounds. Naarden, a small town, forms the key of all the water communications of Holland.

3058. *North Brabant*, comprising that which was the Dutch part of the province, is a flat, sandy, marshy tract, not distinguished by either the natural fertility or manufacturing industry so conspicuous in the rest of Holland and Belgium. Forming, however, the barrier by which the Dutch maintained their independence, it contains several of the strongest fortresses in Europe, which have indeed the reputation of being almost impregnable. Breda is one of the most conspicuous. After Prince Maurice of Nassau took it by surprise, in 1590, its fortifications were greatly extended, and the surrounding country, being intersected by rivers and marshes, can be laid under water. It is an agreeable city, commanding from the ramparts a fine view, and both its church and its town-hall are admired Gothic edifices. Bois le Duc, on the Dommel, so named from an old hunting-wood of the Dukes of Brabant, is a large town, and equally strong. It is so intersected by canals, that eighty bridges are required to cross them; in winter the place is entirely surrounded by water, and can be approached only in boats. Bergen-op-Zoom, farther to the west, is similar as to strength, and was esteemed the masterpiece of the celebrated Cohorn. The glorious but disastrous attack made upon it by the British in the last war is well remembered.

3059. *The outer provinces* of Guelderland, Friesland, Overijssel, Drenthe, and Gröningen, which lie between the Zuyder Zee and the Ems, are rather appendages than integral portions of Holland, and form by their situation part of the great level plain of northern Germany. The country is similar to Holland, however, in its aspect and the general state of cultivation, though a somewhat greater proportion of the land is employed in the raising of grain. Friesland has a very fine breed of horses and horned cattle; and the linen manufacture flourishes to a considerable extent. In these provinces, however, particularly in Guelderland and Overijssel, there is a large extent of sandy and marshy ground, which is not forced into cultivation with the same minute care as in the central provinces. Much benefit, however, is expected from the pauper colonies lately established there.

3060. *The towns of this region* are pretty numerous and considerable, though none are of the first class. Nimeguen, in Guelderland, is ancient, strong, and handsome, commanding a noble view over the Rhine. Zutphen is an old imperial city, dreadfully pillaged in 1572 by the Duke of Alva. It has a magnificent church; and the fens round it have been so completely drained, as to render the air no longer unwholesome. Arnheim is a large and beautiful town, at the foot of the hills of Veluwe, and forming a great thoroughfare into Germany. Deventer, in Overijssel, is an ancient member of the Hanseatic league, and has a venerable cathedral. Zwoll, on the Yssel, is strong, large, and well built. Assen, though capital of the new province of Drenthe, is only a village. In Friesland, Leuwarden, on the Ee, is a large and populous town, in a country surrounded and intersected with canals, which enable it to communicate with the sea, and to carry on a considerable trade. Campen, an ancient Hanse town, has lost its importance, the harbour being now choked up. Harlingen, Franeker, Dokum, Bolswaert, are ports on the Zuyder Zee, and manufacturing places of some importance. Gröningen, capital of the province of the same name, is the most important of all the towns east of the Zuyder Zee. It is well built, and adorned with noble edifices; and its university was once a distinguished place among Dutch seminaries, but is now seldom attended by more than 100 students. Large vessels can ascend the Hunse from the Zuyder Zee.

3061. *Luxemburg*, an extensive province, though political revolutions attached it to the Netherlands, and now to Holland, forms part of Germany, entitling the king to a vote in the Germanic diet. Its character is every way in decided contrast to the rest of Holland and Belgium. Instead of a dead, rich flat, traversed by navigable streams and canals, Luxem-

burg presents almost throughout high mountains and woods, forming scenes of savage grandeur, similar, though on a smaller scale, to those of Switzerland. The country is destitute of water communications, is imperfectly cultivated, and does not contain a population of more than sixty-six to the square mile. Its breeds of cattle and sheep are of small size; but, as usual in mountain pastures, of delicate flavour. The horses are active and hardy; and the tract which borders on the Moselle produces valuable wine.

3062. *The cities and towns* are by no means on the same scale as those in the rest of the kingdom. *Luxemburg*, the capital, situated on two rocks, whose steep sides form a glacis, while the river Else, at their feet, serves as a wet ditch, is one of the strongest fortresses in Europe. The horse and cattle markets are considerable. *Theux* has in its neighbourhood mines of a beautiful black marble; and *Stavelot* carries on a considerable trade in leather. *Maestricht*, the principal town of *Limburg*, has, along with all the part of that province east of the Meuse, been assigned to Holland. It is large, handsome, and well fortified. *Ruremonde* and *Venlo*, also neat towns of some strength, are included in the same district.

CHAP. XII.

HUNGARY.

3063. *Hungary*, called by the Germans *Ungarn*, with Transylvania, Sclavonia, Croatia, and the Bannat, forms a wide range of territory. Long the grand field of conflict between the Ottoman and Christian powers, it was finally possessed by the latter, and has for several centuries formed an integral and important part of the hereditary states of the house of Austria; which has recently annexed to it the portion of Dalmatia obtained from Venice.

SECT. I. *General Outline and Aspect.*

3064. *Hungary* is bounded on the west by Germany; on the south and east by the tributary Turkish provinces of Bosnia, Servia, Wallachia, and Moldavia; on the north, by the Carpathian mountains, which separate it from Poland. It forms nearly a square of 400 miles in each direction, comprehending, with all its appendant states, an area of 133,000 square miles, inhabited by upwards of 12,000,000 people.

3065. *Surface.* The great mountain girdle of the Carpathians ranges nearly in a semicircle round the northern and eastern border of Hungary. Several connected chains penetrate into the heart of the country, of which the most elevated are those of Tatra and Matra; the Julian Alps, and the mountains of the Bannat, on the southern border, render a great part of the country at least very hilly. On the other hand, there are plains of almost boundless extent, such as that to the east of the Danube, watered by the Teisse, which covers a space of upwards of 22,000 square miles; and another to the west of that river, reaching to the borders of Styria. Hungary, protected by the Carpathians from the blasts of the north, and sloping downwards to the south, enjoys a milder climate than any part of Germany. On the Carpathian terraces, particularly, the richest wines, and the choicest productions of southern Europe, are raised in perfection. There is a vast variety of country, however; many tracts being naked and rocky, others covered with marshes, and some even forming deserts of barren sand.

3066. *The rivers of Hungary* are very important. The Danube, making a grand circuit, rolls through it, chiefly from north to south, and receives here its mightiest tributaries. The Drave and the Save, from the east, bring to it all the waters of the great alpine border of Southern Germany. The Teisse, after collecting, in a course of 400 miles, nearly all the streams which flow from the Carpathians, falls in from the east, near the southern frontier. The Maros is the greatest tributary of the Teisse; and the Gran and the Waag are considerable streams, which flow into the Danube itself.

3067. *The lakes of Hungary* are numerous, but only two are large; the Platten or Balaton, which receives the waters of nine streams, and is supposed to pour them under ground into the Danube; and the Neusiedler, the water of which is salt. The long and sluggish streams of the Teisse and the Maros spread into wide morasses, which, acted on by the rays of a burning sun, exhale pestilential vapours, often more fatal than the sword to the armies which have been led into their vicinity.

SECT. II. *Natural Geography.*SUBSECT. 1. *Geology.*

3068. I. *Primitive rocks.* Primitive rocks are not abundant, and they do not occupy great tracts in the districts where they occur. They form the group of Presburg, the group of Nyitra, that of Tatra, to the south of which are situated the mountains of Gomor, of which they form the principal mass. They re-appear in Transylvania on the frontiers of Buckovina and Moldavia; to the south, in the chain of Fagaras, which ranges into the Bannat; to the west, in the mountains of Gaina and Bibar. They re-appear at Peterwaradin, and on the frontiers of Styria. A *central granite* appears to form the group of Presburg; the Krivan in the group of Ostrosky; of Polana, a little farther to the north; and the Tatra. Gneiss, containing beds of granite, of mica slate, &c., occurs in the mountainous parts of the county of Gomor, at the foot of the Tatra, on the frontiers of Buckovina, in the group of Fagaras, in the Bannat. *Mica slate* and *clay slate* occur on the acclivities of all the groups, the rocks of which have been already enumerated. Mica slate forms the group of Nyitra; it is very abundant in the mountains of Zeleznik, Jolsva, Rosenau (in the county of Gomor), where we observe it passing into clay slate, which rock often alternates with it, and at length becomes predominant, forming the whole superior part of the deposit.

3069. *Mercury* occurs at Szlana, in unctuous mica slate: *rhomboidal iron ore*, or iron glance, in the mountains of Ensiedel and Golnitz; *prismatic iron ore*, or hydrate of iron, in beds in clay slate at Zeleznik, and in the vicinity of Rosenau.

3070. *Euphotide*, or *diallage rock*, and *serpentine*, are found at Dobschau, and in the mountains which form the eastern point of Esclavonia and Peterwaradin.

3071. *Porphyritic greenstone* is met with in the upper part of the valley of Tiszolez, where the castle is situated.

3072. II. *Transition rocks.* The rocks of this class begin at Presburg, where they rest on the primitive group: they range from S. W. to N. E. into Galicia, in their course passing behind the Tatra; they cover a considerable space from north to south, where they join the group of Nyitra, the mountains of Zolyom and Gomor. They form the small group of Diosgyor to the north of Erlau; they appear in different points of the chain of sandstone which extends from Tatra into Transylvania; they become more abundant in Marmaros, on the eastern frontier of Transylvania, where they join again with the chain of Fagaras. We meet with them again in the countries of Nagy-Ag and Offenbanya, in the Bannat; and, lastly, in Croatia.

3073. *Deposits of transition quartz sandstone*, and *compact limestone*, with greywacke, occur near to Neusohl, in the group of Tatra, and on the borders of Dunajec, towards the frontiers of Galicia; but this compact limestone occurs alone in a great number of places, where it also terminates the transition deposits.

3074. *Transition syenite* and *porphyritic greenstone* are found at Pila near to Königsberg, at Schemnitz, Kremnitz, in the mountains of Borsony, of Karancs, on the northern foot of the Matra. It re-appears in the mountains of Kapnick, of Nagy-Ag, Zalathna, Voros-Patak; and it appears also to occur in the Bannat.

3075. III. *Secondary rocks.* The following secondary deposits are described as occurring in Hungary:—

1. *The coal formation* rests upon transition strata at Jablunicza and Steurdorf, near to Oravicza, in the Bannat; and the same formation occurs at Fünfkirchen,

2. *The Jura limestone formation* occurs principally in the south-western parts of Hungary.

3. *A sandstone formation*, containing coal, the *sandstone of the Carpathians*, which, in the regular succession, lies upon the Jura limestone, and below the chalk formation, forms the whole chain extending from the foot of the Tatra into Moldavia; it also penetrates into Transylvania, of which it occupies all the central part; it also forms the Kahlengebirge, near to Vienna, where it appears to be connected with the coal formation and old red sandstone of Moravia.

4. *The chalk formation* also occurs in Hungary: thus a remarkable kind of this deposit appears at Ofen and Buda Oros, and a particular compact marly limestone, abounding in green talcy disseminated parts, which may be referred to this chalk, occurs in Transylvania.

3076. IV. *Tertiary rocks.* Molasse, or sandstone with lignite, is the most abundant of the Hungarian tertiary rocks, and covers at the same time the secondary rocks and the conglomerates belonging to trachyte. It covers the southern declivity of all the mountains which form the north-western part of Hungary; it extends into Galicia, at the foot of the Carpathians; it is found in the centre of Transylvania, at Clausenburg, Carlsburg, Hermanstadt, and Cronstadt. It covers, towards the west, the foot of the mountains which form the western limit of that principality, and extends even into the Bannat; it forms nearly the whole south-western part of Hungary, from whence it extends into Croatia. The *coarse marine limestone of Paris* occurs in the neighbourhood of Buda and Eedenburg, on the banks of the Lake Balaton, and at Fünfkirchen. It occurs also in Buckovina, and in Eastern Galicia. The *limestone containing lymneæ* occurs at Nagy-Vasony, and in the marshes of the great plain of Hungary.

3077. *Tertiary Plutonian rocks. Trachyte.* This Plutonian rock appears to rise through the tertiary deposits, and is therefore to be considered as having been sent from below after the deposition of these strata. It forms five groups; one occupies the districts of Schemnitz, Kremnitz, and Königsberg; the second occurs to the north of the Danube, where it forms the mountains of Dregeley and Vissegrade; a third forms the mountains of Matra, on the northern border of the great plain; a fourth includes the mountains between Eperies and Tokay; lastly, a fifth occurs at Vihorlet, and extends into the counties of Ungh and Beregh. The same formation forms a considerable group in Transylvania, on the frontiers of Moldavia; and every thing seems to indicate that it will also be found in the district of Nagy-Ag and Zalathna. The porphyritic variety of trachyte is the most abundant; the other varieties occur only in the Schemnitz group. Pitchstone, pearlstone, pumice, and obsidian occur, associated with the trachyte, around the trachyte hills; and, extending from them into the plains, there are vast beds of trachyte conglomerates or tuffas. These conglomerates are formed of debris, often transported and triturated in water. Near to the hills, they are composed of very large blocks, but in the plains of scoriaceous and earthy matters; and, lastly, of a pumiceous matter, sometimes, ground down into an earthy form. These deposits contain fossil organic remains; viz., opaline wood, impressions of plants and shells of various kinds. The trachytic conglomerates are the principal repository of precious opal, and the pumiceous conglomerates that of jasper-opal and wood-opal. The conglomerates composed of broken down and decomposed pumice are very abundant between Tokay and Tolesva. The porphyroidal varieties form the mountains between Erdo-Benye and Tallya; they appear again in the county of Beregh, where they contain considerable masses of aluminous rock. The auriferous deposits of the trachyte formation are found in masses in the pumiceous conglomerate, or in veins in the vesicular variety of trachyte which is used for mill-stones.

3078. *V. Alluvial rocks.* Old alluvial rocks, and also those of modern formation, abound in Hungary. Of these, the most interesting are the calcareous tuffas, some of which are diluvial, others modern, and daily forming.

SUBSECT. 2. and 3. *Botany and Zoology.*

3079. *The Botany and Zoology* of Hungary are similar to those of Germany.

SECT. III. *Historical Geography.*

3080. *To the Romans* Hungary was known under the name of Pannonia, and was the domain of tribes still more rude, wild, and wandering than those of ancient Germany. The Romans formed out of it the province of Dacia, including the district lying south of the Danube, which, for a lengthened period, was the bulwark and boundary of their empire in this quarter. The fatal step of allowing a passage, in the fourth century, to the flying Ostrogoths, laid open the defenceless empire; and, from time to time, a continued torrent of barbarous invaders poured in from the extremities of eastern Europe, and even of central Asia.

3081. *The Huns*, in A. D. 433, established themselves in this country, which from them has ever since retained the name of Hungary. Attila, whom Gibbon has styled the supreme monarch of the barbarians, established his court and camp on the Teisse and the Danube. In the ninth century followed the Magyars, whose posterity form still the ruling body in the nation.

3082. *Hungary was erected into a kingdom*, partly hereditary, and partly elective, in A. D. 1000. Its most powerful monarch was Louis the Great, who, in the fourteenth century, carried his arms into Italy.

3083. *The union with Austria* took place in 1438, through the marriage of Albert of Austria with Elizabeth, heiress of the deceased king. The crown was afterwards held for a time by Ladislaus king of Poland, and by the gallant chiefs Huniades and Matthias Corvinus; but it ultimately reverted to, and remained with, the house of Austria. Dreadful wars were, however, waged with the Turks, who repeatedly ravaged the whole kingdom, and even laid siege to Vienna; but, for more than a century, that declining power has been completely expelled from Hungary, and has considered it quite enough to preserve its own borders from Austrian invasion.

SECT. IV. *Political Geography.*

3084. *The political relations* of Hungary, considered as a member of the Austrian empire, have been already considered. It has, however, some features peculiar to itself. The kingdom is now hereditary in the Austrian dynasty; but, in case that should become extinct, the right of choice would return to the nation. The Hungarian Diet possesses high prerogatives. Without their vote the king cannot make or change the laws, impose taxes, or even levy troops. Every new king, before his coronation, must take an oath to maintain the constitution of Hungary. The diet consists of four states or orders: — 1. The

bishops and abbots. 2. The magistrates or great nobles. 3. The knights. 4. The free cities. The two former appear in person, and constitute what is called the magnate table, the two latter, who form what is called the state table, appear by their representatives. The diet assembles every three years, at Presburg or Buda, and sits during the king's pleasure. If three of the orders agree to any proposition, the fourth must give its consent.

3085. *In the administration*, the body of the people, with the exception of those who form part of the corporations in the free cities, have no share: a circumstance of which advantage is taken to throw upon them the whole burden of taxation, from which the nobles and clergy hold themselves exempt. The peasantry, though nominally emancipated, are still really held in a state of predial slavery. They are allowed, indeed, a considerable extent of ground; from thirty to forty acres each. Out of the produce, however, the occupant has to pay one tenth to the church, and one-ninth to his landlord, who also claims one hundred and four days' labour in the year, besides sundry other little gifts and services, which are liable to indefinite overcharge. They are also required to co-operate in the making and repairing the roads, and have troops quartered upon them. On the whole, their condition appears decidedly the worse for the privileges enjoyed by a proud and turbulent aristocracy, who have always resisted every measure proposed by the sovereign to ameliorate the condition of the great body of the people.

3086. *The army*, in time of peace, amounts to about 100,000 men, and in time of war it is increased to about 235,000. The expense is defrayed by a peculiar tax, called *kriegssteuer*, or war-tax. The revenue is supposed to amount to about 20,000,000 florins.

SECT. V. *Productive Industry.*

3087. *The agriculture of Hungary*, notwithstanding the rude manner in which it is conducted, and the extent of unfavourable soil, yields very copious products, out of which a large surplus arises for the supply of the neighbouring countries. According to an estimate which Grellman has founded on the *cadastre* instituted by Joseph II., it contains 23,905,000 jochs of productive land, out of an entire surface of 39,329,000; the rest being waste, water, and morass, or otherwise useless. Among these are about 5,000,000 arable, 7,500,000 pasture, 9,000,000 woodland, 1,000,000 vines, and 600,000 garden ground. Schwartner and Blumenbach agree in rating the produce in grain at 105,000,000 bushels. A little maize and rice is grown in the Bannat; otherwise the kinds of grain are those used in Germany. The agriculture is very rude. Light carts; a plough, of which the share is almost horizontal, and which seldom penetrates above three inches; and meagre cattle, present themselves in the dirty farm-yard (*fig. 403.*). In the rotation of crops, every third

HUNGARIAN FARM-YARD.

year is fallow. Cattle and sheep are bred, and even exported, in vast numbers; though the breeds, before late improvements, were by no means distinguished. The horned cattle, however, are large, vigorous, and active, of a dirty white colour, and excellently adapted for the plough. The breed of horses had fallen into total disrepute, till it was improved by the pains bestowed upon

the imperial stud. The native Hungarian sheep bears very coarse wool: but in all the western districts it is much improved by crosses with the Spanish. Some of it is now very fine, and is even imported into England as the best Saxon wool. In 1810, there were found 451,000 horses, 2,400,000 oxen and cows, and 8,000,000 sheep; now probably more. Besides the ample supply of bacon, which is found at the table of almost every peasant, the number of hogs annually exported is from 200,000 to 250,000. Wine is a special object of Hungarian culture. That which bears the name of Tokay, and is produced there, and in a number of surrounding districts, is most celebrated. It is sweetish, luscious, and does not attain to perfection till it is very old. A good deal of the superior richness of the finer sorts is derived, according to Dr. Townson, from mixing the essence or juice of a small number of half-dried and shrivelled grapes with the ordinary wine of the country. Two sorts are produced in this way, *ausbruch* and *mazchlap*; the only difference between them being, that for each pint of essence put into the *mazchlap*, two are put into the *ausbruch*. Tokay is consumed chiefly at the tables of the great Hungarian, Polish, and Austrian nobles. The total annual produce of the Hungarian vineyards is estimated at about 18,000,000 eimers. The Hungarians make their wines a subject

of especial pride, absurdly pretending that the worst is superior to the best French wine. Tobacco is cultivated to a greater extent than in any other European country, and is largely exported. Hemp, flax, and madder are also staple products. Bees are very extensively reared; and the exports of honey and wax are estimated at about 250,000*l*. To these articles may be added, though no longer to the same great extent as formerly, cabbage and other garden products, with some fruits, as plums and melons.

3088. *Manufactures*, in the sense understood in England, can scarcely be said to exist in Hungary. There are, however, coarse domestic fabrics of linen and woollen for home consumption. Hides and skins are tanned, after a simple process, and on a small scale, chiefly by the peasants.

3089. *The subterraneous wealth of Hungary* is equally copious with that which its surface yields. Gold and silver, in particular, the most brilliant and precious of the metals, are raised from the mines of Schemnitz and Kremnitz in greater abundance than in any other part of Europe. The mines are chiefly royal property, or, where private individuals are allowed to collect the ore, they must, at least, give it to the royal smelting-houses at a fixed rate. The annual quantity is stated by Hassel at 1050 lbs. of gold, and 41,600 lbs. of silver. There is a great reduction of the former quantity, partly owing to the exhaustion of the mines, and partly to the poverty of the Austrian government, which can no

longer afford to make the same exertions. According to Delius, the value of the gold and silver extracted between 1740 and 1773 was upwards of ten millions sterling. The engine employed at Schemnitz (*fig. 404.*), for drawing up the ore, and letting down machinery, is moved by water, and was considered the finest existing, before the invention of the steam-engine. The mines of Hungary yield also 10,000 tons of iron, 19,000 tons of copper, 1225 tons of lead, besides a great quantity of coal and salt. According to Hassel, the entire number of miners and labourers employed amounts to 45,000.

MACHINE FOR WORKING MINES.

3090. *Fishery*. The rivers and lakes of Hungary are full of fish; and the fishery is of considerable importance and value. The Teisse is said by the inhabitants to consist of two parts, one of fish and one of water. In 1810, the importations of fish from Hungary into Lower Austria were estimated at 86,000*l*.

3091. *The commerce of Hungary*, notwithstanding its fine rivers, labours under great disadvantages, from the want of sea-coast, from the navigation of the Danube being frequently impeded, and from its embouchure being in the possession of the Turks, whose barbarism has hitherto baffled every attempt to open a communication with the Black Sea. The inland traffic is tolerably brisk, and the roads are continually covered with animals, and with waggons, driven by the Jews, gipsies, and other foreign races, to the 2000 fairs which are annually held throughout the country. The great centres of this internal traffic are Pesth and Debretzen. The exterior commerce of Hungary consists in the exchange of rude for manufactured produce. In 1802, the leading exports were, cattle, 8,483,000 florins; grain, 2,367,000; wine, 2,381,000; wool, 5,039,000; leather, 1,245,000; which, with minor articles, made 24,515,000. The leading imports were, woollen cloth, 4,668,000; cottons, 1,611,000; linens, 2,692,000; silk, 1,223,000; coffee, &c. 2,790,000; hardware, &c., 1,299,000; making, with minor articles, 18,390,000 florins.

SECT. VI. *Civil and Social State.*

3092. *The following* is a statement of the progressive population of Hungary and its dependencies, as deduced from the conscription lists:—

Places.	Date.	Population.	Date.	Population.	Date.	Population.	Date.	Population.
Hungary	1785	7,098,574	1805	7,961,414	1817	8,063,680	1829	9,659,686
Transylvania	1786	1,416,035	1811	1,501,406	1817	1,664,800	—	2,027,566
Military limits	1803	871,237	1807	911,760	1815	940,598	—	924,315
Dalmatia	1807	256,863	—	—	1817	304,055	—	329,727
		9,642,709		10,374,580		10,978,133		12,941,294

3093. *If these returns may be depended upon, they show a gradual and considerable augmentation. The apparent diminution of the population within the military limits was occasioned, we believe, by a transference of territory.*

3094. *The Hungarians consist chiefly of two races, the Magyars, or ruling race, who are estimated by Csaplovicz at 3,500,000; and the Slavonians, the subject people, at 4,050,000. There are also 640,000 Wallachians; 577,000 Germans; 170,000 Jews; 50,000 gipsies; besides Arnauts, Greeks, Armenians, &c. There is no middle class in Hungary. Society consists of haughty nobles, poor peasants, and peddling traffickers. The nobles are a brave, generous, and hardy race. To them applies Voltaire's character of the Hungarians, as "a proud and generous nation, the scourge of its tyrants, and the defender of its sovereigns." They have the most devoted attachment to their ancient privileges and customs, and to every thing Hungarian; the most rooted dislike of the Germans and every thing German. The peasantry present an uniform aspect of rudeness and barbarism, not one being advanced beyond another, nor the whole beyond what they were in a remote age. It is impossible, according to Mr. Sherer, that when the Romans invaded Illyria, the peasants could, as respects dress, aspect, and manners, be more completely barbarous than at present; nor could the waggons of the Scythian camp be ruder than those which still crowd the streets of Presburg. The traffic is chiefly carried on by Germans, Jews, and the gipsies, a numerous race, who present the same aspect as in other parts of Europe.*

3095. *In respect of religious worship, full freedom has been long established in Hungary, and all Christian professions are considered equal in the eye of the law; but, in practice, it is complained that this equality does not go beyond toleration. The Catholic is the most numerous and powerful; its professors are estimated by Csaplovicz at about 5,000,000; at the head of whom are three archbishops, thirty-nine bishops, twenty-two abbots, and about 9300 clergymen, secular and regular. The Protestants amount to about 2,100,000, and have 1867 clergymen. The Greeks amount to 629,284, and have an archbishop, three bishops, and nearly 4000 clergy. The bishops possess extensive property, and are bound to take the field with their vassals in the national insurrection. Seven bishops were killed in the battle of Mohatz. Schwartner estimated the Hungarian clergy at 15,600; which, taking the population at 9,600,000, gives one clergyman for every 610 individuals.*

3096. *Learning is not altogether neglected in Hungary. Latin is, in some places, the ordinary language of the higher ranks, and mathematics and natural history meet with encouragement. There are only fifty-eight printing presses, and sixty paper manufactories in the kingdom. Such is the want of information, that Dr. Bright found the leading people at Schemnitz impressed with the belief that Mexico was an English island, and that sugar and coffee grew in Great Britain! Hungary, however, has a university, with a library of 60,000 volumes, and a valuable museum. In 1820, it was attended by 985 students. According to Dr. Bright, many of the nobles are exceedingly anxious to promote the intellectual improvement of their countrymen.*

3097. *The amusements of the body of the people consist chiefly of some national dances, particularly on occasion of the vintage, which is a season of unbounded gaiety. The national military dress being the same commonly denominated hussar, is picturesque and martial, and has been imitated by the other European nations. The peasantry wear a broad-brimmed varnished hat, with a low rounded crown; they have their matted long black hair negligently plaited or tied in knots, a blue jacket and trousers covered with a cloak of coarse woollen cloth or sheepskin, still retaining its wool. They live in small villages, or rather clusters of cottages, arranged on each side of a muddy road, whitewashed, roofed with thatch, but the interior containing, generally, three tolerably comfortable apartments.*

SECT. VII. *Local Geography.*

3098. *Hungary is divided into, 1. Lower Hungary, which forms the western; and, 2. Upper Hungary, which forms the eastern part of the kingdom. 3. Croatia. 4. Slavonia.*

3099. *Upper Hungary is divided into two parts by the Danube. That on the north of the river is the most important; and contains both the leading capitals and the great mining districts of Schemnitz and Kremnitz.*

3100. *Presburg, established, in 1536, as the place where the kings were to be crowned, and the diets to be held, passes often as the capital of Hungary, though it is neither so large nor so handsome a city as Buda. Csaplovicz estimates its population at 32,026. The houses and streets are ordinary in their appearance; and the suburbs only can boast a few palaces of the nobles. The castle, lately burned down, except the walls, overlooks the very extensive plain in which the city stands. Presburg has a few manufactures, and a considerable trade, chiefly in corn and wine, up and down the Danube. There is a large Lutheran seminary, attended by about 500 students.*

Buda, or Ofen (fig. 405.), and Pesth, separated by the Danube, form, in conjunction, by

much the most important city in Hungary. Buda, on the right bank, is the first in dignity, being now the seat of government, which was transferred thither by Joseph II. from

BUDA.

Presburg, in 1784. It consists chiefly of an extensive fortress seated on a lofty rock, somewhat resembling the castle of Edinburgh, and containing the houses of the Palatine and of some of the principal nobility. Along the foot of the castle several streets extend upon the river. One of the most remarkable features consists of the baths, which are ancient, and of Turkish construction. The citizens resort to them in crowds, exhibiting

themselves in a very unscrupulous state of nudity. Pesth, on the opposite bank, is a larger and now more important city, forming the centre of the inland trade of Hungary. Four immense fairs are held there, which present an epitome both of the people and productions of the country. The native products are chiefly sold without the city, on both sides of a long road, as they arrive in the waggons, disposed for that purpose so as to form a species of square enclosure. An immense space is covered with horses, sheep, and cattle, the latter often amounting to 30,000. The goods brought down from Vienna are displayed in a large open space within the town, and in ranges of booths, which are penetrated by two broad streets crossing each other at right angles, and by other smaller streets and passages. The Danube, also, for the space of half a mile, is covered with boats and barges, which, with the banks, serve as a market-place for the goods. For recreation are prepared various sights, puppets-shows, fruits, especially water melons in immense quantities, and refreshments cooked and presented by the gipsies. Great commercial roads branch off from Pesth through every part of the country, and towards Austria, Moravia, Galicia, Transylvania, Croatia, and Italy. Pesth contains 61,502 inhabitants, and Buda 27,470; making in all 88,972. Pesth is chiefly modern, and well built; containing many good streets and handsome houses, besides churches. There is considerable magnificence in the grenadiers' caserne, built by Charles VI., and in a large unfinished edifice, raised by Joseph II., which Townson calls a palace; but Bright does not think it possible to say what it is. The national university, already mentioned, is in Pesth. The city is without walls, and is connected with Buda by a bridge of forty-seven boats, which are moveable, and through which, at stated times, an opening is made to allow the passage of vessels and rafts. In winter it is taken down, and the two cities communicate over the ice.

3101. *The mining capitals*, Schemnitz, Kremnitz, and Neusatz, are situated on the declivities of a bold and mountainous country, forming a lower ridge of the Carpathians. Schemnitz, the great centre of the mining operations, is in a position peculiarly rugged, the streets being built along the sides of hills, and separated from each other by cliffs and woods: of its 17,000 inhabitants, 8500 are employed in the mines. The town was founded in 745; but it was Maria Theresa who established the mining college, which is conducted on a very liberal footing; comprehends lectures on every branch of natural knowledge; and is attended, even in bad times, by 200 or 300 students. The mines have been already

noticed. The water is drained off by a subterraneous stream of about twelve miles in length, which empties itself into the river Gran. Kremnitz (*fig. 406.*) is only about half the size, and has a more straggling and neglected appearance; though one of its churches is very profusely ornamented. Neusatz, about the size of Gran, is supported by the copper-mines, and has a large manufactory of arms in its vicinity.

KREMnitz.

3102. *There are also other towns of some importance* in this division of Lower Hungary. Gran, on the Danube, was once a military post of the first importance, though its strong castle is now in ruins; but it is still the ecclesiastical capital, its archbishop being the primate and chancellor of the kingdom. Mineral waters, resembling those of Epsom, have also been lately discovered there, from which a manufactory of magnesia has been established. This

district extends also along the lower course of the Danube, on its eastern bank, where it approaches the Turkish frontier. Here occur several large towns. Theresopol, named after Maria Theresa, in a wide plain, with 30,000 inhabitants; Neusatz, a free city on the Danube, with 17,000 inhabitants, and a considerable trade with Turkey; Zambor, not far from the Frunz canal, with 18,776 inhabitants, and a large trade in corn and cattle. The bulk of the inhabitants in all these three towns consists of Greeks and Servians.

3103. *That part of Lower Hungary which lies to the south-west of the Danube*, enclosed between that river and the Austrian and Illyrian frontiers, contains also a number of places of considerable importance. Edeburg, sometimes spelt and pronounced Edinburg, is finely situated in a country variegated with wooded and vine-covered hills, which surround the great lake of the Neusiedler See. Of 11,487 inhabitants, 4600 are Protestants. There is more manufacturing industry than in most Hungarian towns; but still it owes its main prosperity to its position; being the route by which supplies of provisions are conveyed from Hungary to Vienna. For this purpose, 40,000 cattle, and 80,000 hogs are annually brought to its markets. There is also a great trade in wine, of which 32,000 eimers are produced in its neighbourhood; and we trust there is little ground for the allegation of Debretzki, that the young ladies who are employed in the sale of it partake rather too copiously of this beverage. Edeburg has also in its neighbourhood a mine of coal, which yields about 12,000 tons annually. Raab, on the river of the same name, near its junction with the Danube, once celebrated as a fortress, is now more noted for its fairs and markets. Of its 16,000 inhabitants, more than half live in the suburbs. Comorn, at the junction of the Danube and the Waag, is still more celebrated for its ancient strength; and so early as the year 1272 it was considered one of the bulwarks of the Austrian monarchy. Its situation gives it still a considerable trade; which, since the year 1805, has caused its population to increase from 9300 to 11,000. It suffered severely by shocks of earthquake in 1763 and 1783. Stuhlweissenberg, in the heart of this marshy district, was anciently a splendid town and a royal residence, called Alba Regalis. For five centuries the kings of Hungary were crowned and their remains deposited here. Since the beginning of the last century, it has been entirely neglected; and though there are a number of buildings which bear the stamp of grandeur, it is but a poor and mean place. It has a population of 18,776. A little to the west of Stuhlweissenberg is the great lake of Balaton or Platten, about eighty miles in length and twelve in breadth, surrounded by vast woods, and by precipitous though not lofty banks. Veszprim, Guns, and Sturamger are small country towns, the last only remarkable by being the seat of a bishop and of a clerical academy. Fünfkirchen is an ancient city, which makes a somewhat magnificent appearance by its ecclesiastical edifices, and its university, which was once attended by 2000 students, and has produced a number of eminent men. The bishop has a good library, of 20,000 volumes, to which the citizens are allowed access; an advantage, however, of which they rarely avail themselves. There are, moreover, a great quantity of hogs and cattle brought for sale to Fünfkirchen. Population above 11,000. Mohatz, on the Danube, is only a large assemblage of cottages; but it is celebrated as the scene of the great battle gained by the Turks in 1526, when Louis II. perished, with twenty-eight magnates, 500 nobles, seven bishops, and 22,000 troops. Szigeth is a strong post, celebrated in Hungarian warfare, situated on the Almas, near its junction with the Danube.

3104. *Upper Hungary* consists of a vast range of territory, extending from the Danube to the eastern boundaries of the kingdom. The hills and mountains of the northern part, being finely watered, produce in the highest perfection those delicious wines for which Hungary is so famous. The southern part consists of one unvaried and almost unlimited plain, through which flows the Teisse, which traverses Upper Hungary from north to south. This plain consists, in some places, of barren sand blown into hillocks; in others, of immense expanses of fine pasturage covered with numberless flocks and herds; while a great part of the tract immediately bordering on the Teisse is marshy and inundated.

3105. *Debretzin, or Debreczin*, for extent and importance, takes decidedly the lead of all places in Upper or Eastern Hungary; yet it may be called an enormous village, rather than a city, or even a town. Population about 40,000. The houses, with scarcely any exceptions, are mere cottages, one story high, roofed with thatch, and arranged on no regular plan. There is no pavement, and in the most frequented quarters the passenger flounders through sand and mud. Instead of a wall, it is surrounded by a hedge, and the town-gates are, like our field-gates, stuck with thorns and brambles. The greater part of the inhabitants are Calvinists; and by their plain attire, their simple deportment, the stillness and earnestness which sits upon every countenance, give a character to the place very different from that of a gay capital; yet, next to Pesth, it is the most commercial town in the kingdom. Every quarter of a year there is a market, when a space of ground which the eye can scarcely command is covered with flocks and waggons, bales and cases, tents and huts. A fine species of soap made here is considered a luxury even at Vienna; and a great deal of saltpetre is manufactured. The Calvinists have an extensive college, attended by 550 students, and possessing a library of 20,000 volumes.

3106. *Among other towns of Upper Hungary* must be mentioned Grosswaradin to the east of Debretzin. It is a pretty frontier town of the district of Hungary inhabited by the Wallachians. The inhabitants, unlike those of Debretzin, are particularly gay; music and dancing are heard in every house; and there are four warm baths, to which the inhabitants resort for pleasure as well as health. Kaschan, in the northern hilly country, is called by Townson the metropolis of Upper Hungary, but does not seem to be at present considered in that light, nor can it any way rival Debretzin: it contains 15,500 inhabitants. The principal street is broad and pretty regular, adorned with some good houses of the nobility, an elegant coffee-house, and a fine Gothic church. At about a day's journey is a mountain, which produces that fine stone the true opal, which, as some suspect, is found nowhere else in the world; those called the oriental being alleged to be all brought from this mine. Erlau, or Agria, a larger town, but ill-built, is the seat of a richly endowed archbishopric; one of the late incumbents of which, otherwise not much extolled by Townson, founded a very handsome college. Mischkoks is also a large town in the same neighbourhood, in a rich wine and fruit country, of which it collects the products; with a population of 21,400. Tokay is only a village; and the surrounding district is only one of a number producing the celebrated wine already mentioned, which bears its name. Szegedin, farther down the Teisse, at its junction with the great tributary of the Maros, is a large and strong city, with 30,000 inhabitants, and a flourishing trade in wool and tobacco, of which 60,000 cwt. are sent down the Danube; salt from Transylvania, and cotton from Macedonia. A Greek protopapa resides here; and there are several seminaries and convents. Temeswar, in the south, the capital of the Bannat, is one of the strongest, and also of the most beautiful, towns in the kingdom. It has a number of public buildings which are admired; as the Gothic cathedral, the Greek church, the synagogue, the military and burgher hospitals. There are some manufactures, and a considerable trade on the Bega canal.

3107. *Croatia* is a district which, though possessing a people and language of its own, has for some time been attached to Hungary, and sends deputies to the Hungarian diet. Since the re-annexation of Carlstadt, which a long time formed part of the kingdom of Illyria, it extends over 3356 square miles, and contains about 370,000 inhabitants. The district of Carlstadt, on the Illyrian frontier, is mountainous; but westward the country declines into a level plain, traversed by the Save. Corn, cattle of small size, and tobacco of good quality, are its staples. The Croats form bodies of light horse rather distinguished in irregular warfare. Agram is a large and strong town, on the Save, without manufactures, but with a good deal of trade, both on the river and between Hungary and the Adriatic. Population, 17,000. Varesdin and Carlstadt are smaller places, deriving some importance from being in this last line of commerce.

3108. *Sclavonia* is a district to the east of Croatia, and the only one bearing the name of a nation whose colonies and language are so widely diffused. It enjoys a mild climate and fertile territory, yet more than half of its surface, of 3478 square miles, is covered with wood, and the rest is by no means cultivated to the extent of which it is capable. Its political relations are in many respects the same as those of Croatia; its products and trade similar, and it is equally destitute of manufacturing industry. Posega is accounted the capital; but Essek, a strong place on the Drave, near its junction with the Danube, is of more importance.

3109. *Transylvania*, meaning the country beyond the Carpathian hill forests, and called by the Germans *Siebenbürgen*, (a name brought by German colonists from Siebengebirge, near the Rhine,) is a very elevated territory: the Carpathians, which enclose it in the form of a half moon, present summits of 7000 or 8000 feet. To the height of 5000 feet they are covered with wood, but beyond that altitude they are rugged and alpine. The mountains are perforated by numerous caves. There are many little lakes; and the morass of Kovaszna is remarkable for its almost unfathomable depth. Notwithstanding its rugged surface, Transylvania has a mild climate, and is well cultivated. Its produce in grain is reckoned about 17,000,000 bushels. Cattle form a principal staple: the flesh of the oxen is good; but the milch cows are not of great excellence, and the wool of the sheep is coarse. Wine is produced in abundance, to the extent of 3,640,000 eimers, according to Blumenbach; but, as it does not keep, it is not an object of trade. Transylvania is rich in minerals, particularly gold, of which it yields 2750 marks; also 3500 tons of iron. It might supply the whole empire with salt; and sends, in fact, 25,000 tons into Hungary. The miners, chiefly German, amounted, in 1791, to 4328. There are no manufactures, except the most common fabrics. The people consist almost entirely of strangers, who have immigrated from the neighbouring and distant countries. Lichtenstein reckons 828,165 Magyars, 302,000 Saxons, and 507,700 Wallachians; which, with other small sects, made up, in 1817, a population of 1,664,800. In 1829, the number appears to have risen to 2,027,566. The Protestants predominate in Transylvania; amounting, by Hassel's enumeration, to 348,000, with 40,000 Unitarians; while the Catholics are 110,000, and the Greeks 150,000. These, we presume, are heads of families, as otherwise they would not nearly

compose the amount of the population. The religious professions have each seminaries for rearing their respective students; and there are two societies for the culture of the Hungarian language and history, both established by Count George Banky. Hermanstadt, situated in the Saxon district, and considered the capital, is surrounded with a double wall, and contains 16,000 inhabitants, an extensive Lutheran seminary, two public libraries, comprising 20,000 volumes, a picture gallery, and a national museum. Cronstadt, however, also Saxon, and on the most eastern frontier, is a still larger place, containing 25,000 inhabitants, with various little manufactures, and enjoying very extensive intercourse with Turkey and Greece, to the amount of 1,000,000*l.* sterling. Clausenburg, near the western frontier, is a large open town, containing three seminaries, catholic, Lutheran, and unitarian, attended by about 1200 students. Carlsburg is a smaller town, defended by a strong castle on a hill above the Maros, and honoured by the tombs of the Huniades.

3110. *The military frontier* is a long range of territory, appropriated from the southern border of Croatia, Slavonia, Hungary, and Transylvania, and placed under a peculiar régime, in the view of forming a barrier upon this side against the inroads of the Turks. For this purpose it is placed under a system completely feudal, all the lands being held under the condition that their occupants take the field in person whenever they may be called upon. Each individual receives a certain number of acres, which cannot be sold, pledged, or dismembered, though it may be exchanged for another of equal amount. That his fields may not suffer when he is called out, the inhabitants are divided into families of about sixty, at the head of whom is a directing patriarch, and among whom the culture and produce of the land is in common, each family, according to the number that it has sent out, and their length of service, having allowances or remission of tax of twelve guilders a head. The country is divided, not into provinces, but into regiments; the Carlstadt regiment, the Gradisca regiment, &c. This singular arrangement began with Croatia, in 1566, and ended with Transylvania in 1764. Of late its chief use has been to form a cordon for preventing the irruption of the plague. This frontier partakes physically and morally of the peculiarities of all the countries and all the people from which it is severed. The industry is chiefly pastoral, not much more than a fourth of the lands being under the plough. The cities are called Free Military Communities; but none of them contain 10,000 inhabitants. Semlin, in the Slavonic frontier, is the largest. Peterwaradin, Brod, and Gradisca are strongly fortified little towns.

3111. *Dalmatia* is the rudest province of the Austrian monarchy. It forms a line of coast, about 300 miles in extent, from the border of Illyria to the Gulf of Cattaro, having a long chain of islands running parallel. This coast is bleak and arid, covered with woods and bushes; till, in the interior, it rises into long ranges of bleak and rocky summits. Dalmatia produces scarcely any grain; but its cattle, though small, are numerous: honey is produced in great perfection from the numerous aromatic plants on its hills; the fishery employs 8000 men, and is supposed to produce in value nearly 80,000*l.* The population consists of Morlachians (sometimes called also Dalmatians and Montenegrins), both of

408

SPALATRO.

Slavonic race, and a mixture of Italians. Zara, the capital, is a little town, on a promontory of land, severed from the continent by so deep an abyss, that there is no communication unless by a bridge. Spalatro (*fig. 408.*) is a larger town, on a little peninsula, strong by art and nature. It contains a

number of large old houses, forming narrow and irregular streets; but it is chiefly distinguished by the remains of the superb palace of Diocletian, one of the grandest monuments of ancient architecture. Pola, once a great and splendid city, is reduced to a vil-

lage, but still contains a most magnificent amphitheatre (*fig. 409.*), in high preservation, one of the most celebrated remains of Roman antiquity. Sebenico, Ragusa, and Cattaro are tolerable seaports, with good harbours; and the latter, on the Turkish border, is an important military position.

409

AMPHITHEATRE OF POLA.

CHAP. XIII.

POLAND, WITH DUCAL PRUSSIA.

3112. *Poland* is a large country, which, though it has been so studiously expunged from the map of Europe, seems still to retain its claim to be considered as separate and distinct. The same physical aspect characterises it, and the people, in their character, their language, and all their national feelings, are still Poles. We do not annex Lombardy to Austria, nor Hanover to Great Britain, because they are ruled by the respective sovereigns of these countries; neither, it should seem, ought the partitioned members of the Polish monarchy to be yet viewed as actually incorporated into the territory of their successful invaders. We shall include Ducal Prussia, as being entirely enclosed by Poland, and participating in all its natural features.

SECT. I. *General Outline and Aspect.*

3113. *Poland* forms a vast level expanse of territory, the most easterly in Europe, except Russia. On the north it is bounded by the Baltic; on the east it has Russia, from which it is divided chiefly by the courses of the Dwina and the Dnieper. On the west it has Germany, mostly the Prussian territories; while on the south it is separated by the Carpathian mountains from Hungary and Transylvania; and it borders also on the tributary provinces of the Turkish empire.

3114. *The surface of Poland* forms part of that immense and unvaried plain which covers the northern portion of all the central European countries. This plain, which includes only about half of France and of Germany, occupies the entire extent of Poland. Even the Carpathian and the Silesian mountains, which border upon it, and shoot branches into it, make scarcely any sensible change in its level immensity. A great portion of this plain is overspread with a deep layer of sand, alternating, however, with large clayey tracts and extensive marshes. A cold and humid atmosphere, a winter nearly as severe as that of Sweden, and violent winds, blowing uninterruptedly over this wide open region, are consequences of this physical structure and position.

3115. *The rivers of Poland* are large, long, and navigable; seldom obstructed by rocks or cataracts. They frequently overflow their low banks, and convert the neighbouring provinces into a sea, communicating to them a luxuriant fertility. They rise, generally, not from mountain chains, but from marshy plains in the interior of the kingdom; and a plateau of almost insensible elevation separates those which direct their courses to the Baltic, from those which flow to the Black Sea. The Vistula, however, the most important and the most decidedly Polish, rises in the mountainous frontier of Silesia, passes Cracow, and, by a winding course to the east and north, reaches Warsaw, where it is augmented by the copious united streams of the Bug and the Narew, flowing from the rich plains to the eastward. It then holds a course almost due north; and, after passing Thorn, enters the sea by two mouths, one of which forms the Frische Haff, the other the great commercial port of Dantzic. The Vistula has a course of upwards of 500 miles, and is one of the most commercial rivers in Europe, being the main channel through which all the produce of Poland passes. The Niemen, more easterly, has almost as long a course; but the poor tracts of Lithuania, through which it flows, afford a much smaller amount of valuable commodities to be brought down to the port of Memel. The Dwina, though not quite so long, is a more valuable river, but, with its port of Riga, is almost entirely Russian. The Dnieper rises amid the marshes in the heart of Poland, and communicates, during the flood, with some of the tributaries of the Vistula; but the greater part of its long course is through Russia. The Dniester also rises from the Carpathians, and waters part of Austrian Poland before it becomes Russian. Even the Pruth, the present boundary of the Russian and Turkish empires, takes its rise in Poland.

3116. *The marshes of Poland* can scarcely be dignified with the name of lakes; though they are extensive, and in the wet season some of the interior provinces almost resemble a sea. Several extensive *haffs*, partaking of the character of lake and bay, occur on the shores of the Baltic, at the mouths of the great rivers.

SECT. II. *Natural Geography.*SUBSECT. 1. *Geology.*

3117. *The Geology* of this country is described with that of Russia.

SUBSECT. 2. *Botany.*

3118. *Poland*, from its situation, and, as may be judged, also, from the nature of the surface of that country, has no peculiar vegetation. The plants it produces are scarcely in any way different from those of the territories which circumscribe it; of Germany on the

one hand, and of Russia on the other. It may have political, but it has no natural boundaries.

SUBJECT. 3. Zoology.

3119. *The zoology of Poland* is essentially the same as that of central Europe, and need not therefore be here dwelt upon. The pigs, like those of Russia, are generally very small, and of a reddish colour.

SECT. III. Historical Geography.

3120. *Poland, in ancient times*, formed the chief portion of that vast plain, called by the Romans Sarmatia, and viewed by them as a still ruder and more barbarous region than Germany. Sarmatia and Scythia are, in their descriptions, always combined together, as the abode of nomadic and savage tribes. The Roman arms penetrated to no part of this immense plain. From the earliest era to which our records ascend, it appears to have been peopled by the tribes called Slavonic; a race widely diffused, distinguished by a peculiar language, by a strong national feeling, and by a particular train of superstitious ideas. Though shepherds, they do not seem to partake the migratory character of either the Teutonic or the Tartar nations. The impulses which actuated them were derived chiefly from the Huns, the Goths, and other nations of Asia, for whom their country was a path to the conquest of western Europe. The Slavonic tribes were long held in the most cruel bondage by these eastern invaders; and their name was employed even to designate the most degraded state to which human nature can be reduced; but many ages have elapsed since they shook off this ignominious yoke.

3121. *The early annals of Poland* are obscure, and possess little interest. In 999, Boleslaus assumed the title of king. The Poles continued a powerful and warlike nation, though dreadfully harassed, for several centuries, by the inroads of the Tartars. In the end of the fourteenth century, the country obtained a most important accession. Hedwig, the heiress of the crown, married Jagellon, grand duke of Lithuania, on condition of that prince embracing Christianity, and incorporating his dominions with those of Poland. Poland thus united, became one of the most powerful monarchies of Europe, and its martial character gave it a commanding influence. The exploits of Sigismund and Sobieski hold a conspicuous place in military history; and Poland, for two centuries, was the main bulwark of Christendom against the alarming progress of Turkish invasion.

3122. *The decline of Poland* may be dated from the beginning of the last century, and may be ascribed, partly to the improvement and augmented influence of Russia and Prussia, but in a far greater degree to the incurable defects in the constitution of the state. The nobles, about 500,000 in number, formed the nation; the rest of the inhabitants being slaves, incapable of acquiring any property in land, without any privileges, and sold, like cattle, with the estates to which they belonged. After the extinction of the princes of the Jagellon line, the power of the nobles became quite illimitable: each of them might aspire to the throne, the sovereign being merely the *first citizen of the order*. Among themselves they formed a perfect democracy, the poorest being, in respect of privileges, quite on a level with the most opulent. They were authorised to maintain troops and fortresses; and were rather, indeed, a sort of independent princes than the subjects of a constitutional monarchy. By a singular absurdity, any one noble might, by interposing his *veto*, suspend the whole deliberations of the diet, and prevent the possibility of their coming to any conclusion. Hence the country was the constant theatre of intestine commotion; and foreign influence and corruption had unbounded scope, not only at the election of sovereigns, but in the whole proceedings of the diets. How much soever we may detest the means by which it was effected, no one can regret the abolition of a system of government which combined all the mischiefs of anarchy without its stimulus to enterprise; which made every landlord a petty despot, and every cultivator a slave.

3123. *The partition of Poland*, justly regarded as one of the most iniquitous measures which have disgraced modern times, was begun in 1772, by Frederick II. of Prussia, and the Empress Catherine II., chiefly, it is believed, at the suggestion of the latter; while Austria was reluctantly dragged into the league. At this time, however, each cut off only a corner, to round their own territories, and Poland remained still extensive, and nearly entire. But nothing was done to repair the defects in the constitution; and the weakness and disunion that prevailed left the country as open as ever to foreign aggression. In 1792, the three powers again joined, and made a fresh partition, which reduced Poland to little more than half her original dimensions. She now roused herself, and made a glorious effort for her deliverance. She saw, and endeavoured, though too late, to obviate, those abuses in her system of government of which she had been the victim. But the partitioning powers had gone too far to recede, and were not to be disappointed of their prey. The Poles, under their hero Kosciuzko, made the most gallant efforts to preserve their independence and their newly acquired liberties. Unfortunately, however, their exertions were unavailing.

They were overpowered by the energies of Suwarrow, and the valour and number of his troops. The Russian general marched direct upon the capital, and, storming the fortress of Praga, to which the patriots had retired as their last hold, extinguished, apparently for ever, the rights and glories of Poland. An entire and final partition was then made, in which Russia had by far the most extensive portion; Prussia, the best situated and most commercial; Austria, on the whole, the most productive.

3124. *Considerable vicissitudes have befallen Poland* since this attempt finally to fix its destiny. Napoleon, after his great victory at Jena, penetrated into the country, and obtained the cession of all which had been given to Prussia at the period of the partition. He erected it into the Duchy of Warsaw, and vested it in the house of Saxony, who had reigned for a considerable time as elective kings of Poland. In his next grand expedition, destined finally to humble the power of Russia, the design of restoring Poland to its existence as a kingdom was openly proclaimed. It was hailed by the Poles, and even by their hero Kosciuzko; and, in supporting it, they displayed, on several occasions, a valour worthy of the most glorious eras of their monarchy. Napoleon, had he conquered, might here have found cordial and attached subjects of his empire. Amid the downfall of his whole usurped power, and the liberation of Europe from the universal monarchy with which it was threatened, the relapse of Poland under its old oppressors was a solitary evil, which was scarcely perceived. The spirit which had been displayed by the Polish nation procured some melioration of its lot. The sovereigns felt that they could not trample with impunity on the feelings of so great and brave a people. Alexander formed the central regions on the Vistula and Bug into a separate state, to which he gave the lost, but still fondly cherished, name of the kingdom of Poland. Austria and Prussia were forced to grant to their portions certain privileges, and a form of representative government before withheld. A recent and gallant attempt of Poland to regain her independence has had a disastrous issue.

SECT. IV. *Political Geography.*

3125. *The political existence of Poland* as a great independent kingdom was finally extinguished by the last fatal partition. The name of the country, however, and the memory of its ancient glories, still live among the people of Poland; and an opportunity to renew its political existence would, it has appeared, be eagerly embraced.

3126. *Among the three partitioning powers, Russia* availed herself of her own strength and favourable circumstances to seize a most unequal and preponderant share. Instructed, however, by the events of the last war, and the spirit displayed by the Polish people, she afterwards affected to pursue a liberal and conciliatory course. The fallen and proscribed name of Poland was revived, and the shadow of their ancient diet was still fondly cherished.

3127. *The modern kingdom* on which Alexander vouchsafed to confer the name of *Poland*, comprises only a small, but fine and fertile, portion of that once mighty monarchy; the rich and cultivated banks of the Vistula, the Bug, and the Narew. In 1829 it contained, on a surface of 2270 German square miles, a population of 4,088,000. A certain form of representation was granted to this kingdom, including even provincial assemblies, which send their deputies to the general diets; but a body which deliberates under the eye of 30,000 foreign troops can enjoy only a precarious exercise of its functions. Yet they did not hesitate to break forth into daring flights, such as their proud ancestors were wont to indulge in; occurrences which soon gave disgust to the emperor, who had granted these privileges under the hope of their being exercised in a very different spirit. The freedom of the press, also, which he at first made a show of granting, was soon employed in a manner so little congenial to his views, that he determined to withdraw it, and restore the abolished censorship. Upon the whole, however, in consequence of this imperfect freedom, the privileges of the different orders were better respected, and property more secure, than in any other part of Poland. It is impossible as yet to foresee what may be the consequence of the late abortive attempt to shake off the yoke. The revenue is estimated at 1,300,000*l.*; and the army, when at its full complement, has been fixed at 30,000 infantry, and 20,000 cavalry.

3128. *Gallicia*, the name which Austria gives to her portion of Poland, has also a form of representation, though, in compliance with the temper of the Austrian government, it rests on a much narrower basis. The states consist of four orders; the clergy, the nobles, the knights, and the representatives of cities: they meet annually; but the imposition of taxes, and the making of laws, the two primary functions of a national assembly, do not lie within their competence. They are allowed, however, some concern in the distribution of the land-tax, and the mode of levying the troops; though the amount of both is fixed by the sole will of the sovereign. The revenues of Gallicia are estimated at about 10,000,000 guilders, of which the extensive salt mines furnish one of the most copious sources.

3129. *Prussian Poland* is now reduced to the grand duchy of Posen, by no means the most fertile or productive part of the kingdom, but valuable from the manner in which it consolidates and connects the detached parts of that scattered monarchy. The people have since obtained provincial states, on the same footing as the other parts of the Prussian dominions. The representation is chiefly of the landed interest, and the king agrees that he will not make any alteration in the laws or taxes without their consent; but any proposed change must originate with him; and, as the debates do not take place in public, we have yet little opportunity to judge of the working of the new system thus established.

SECT. V. *Productive Industry.*

3130. *The industry of Poland* is in a more rude and infant state than that of any other country in Europe, some parts of Russia and Turkey alone excepted.

3131. *Agriculture*, the first and simplest form of industry is that by which alone Poland provides for herself both the necessities and the luxuries of life. Almost every part of the country is under culture; and the plains of Volhynia, Podolia, and of the Upper Vistula, produce good crops of the finest wheat in Europe. This abundance, however, is not the result of any skilful or intelligent labour, or judicious application of capital. The cultivators, within the period of fifty, and in some cases twenty years, were bondmen fixed to the glebe, and toiling in a mechanical round for the profit of their masters. Though now raised to the rank of free labourers, and in many cases having received even a permanent interest in the soil, they have not yet acquired the character suited to this new station, but continue nearly in the same degrading dependence on their landlords as formerly. Each peasant is a species of little farmer, cultivating a small spot with his own hands, and paying the rent partly in kind, and partly in personal service. Wheat is cultivated chiefly on speculation, to supply the richer countries of Europe. In the country where this fine wheat is produced, the body of the people never taste it; and the traveller who passes through Poland can scarcely, unless in the great cities, obtain a loaf of wheaten bread. Rye is the grain almost exclusively cultivated for national subsistence. Hence it is always sure of a market, though at a low rate; but wheat depends upon the state of foreign markets for bringing any price at all. It is raised only on the finest parts of the land; and does not, in Mr. Jacob's opinion, occupy more than one acre in ten. Yet it is to the sale of this wheat that the grandees almost exclusively look for a supply of money, and, through it, of the finer manufactures and foreign luxuries. The recent depression in the prices of grain, and its exclusion for some years from the markets of Britain, reduced the Polish landlords to extreme distress; and, in order to relieve

themselves from embarrassment, they adopted a system of over-cropping, which Mr. Jacob suspects has seriously injured the fertility of many of the lands. But, latterly, the exports from Poland to Britain have again become very great. In 1830 no fewer than 404,000 quarters of wheat were exported from Dantzic, of which 311,000 were for England; and during 1831 the amount was still more considerable.

3132. *Manufactures* are in a state decidedly inferior to that of agriculture. Even the rude fabrics which are almost every where else carried on for domestic use, are wanting in some districts. In others, however, they are conducted with some diligence; particularly in the countries on the Vistula, and those belonging to Prussia. In them, coarse but good linen is made, to an extent which affords a surplus for exportation. Within the last few years the manufacture of woollen cloth has remarkably increased in the new kingdom of Poland. In 1830, it produced 7,000,000 yards, part of which was sent as far as China. The timber, with which the country is so largely covered, affords ample materials for cabinet and wood-work; and this, in the mountain districts, is carried on under its ruder forms; but in the cities are fabricated articles of a more elegant and splendid nature. The manufacture of coaches at Warsaw is extensive, finding a ready market from the pomp and profusion of the Polish nobles.

3133. *The chief and almost only mineral production* of Poland is salt, the deposit of which in the southern provinces is the most copious in Europe, and the mines are more extensively worked than any other in the world. The Carpathian mountains contain also some iron; but the metallic wealth of Poland is, on the whole, unimportant.

3134. *Commerce in Poland* is carried on with some activity, in consequence of the large surplus of rude produce to be disposed of, and the many foreign fabrics and luxuries of which the country stands in need. Its grain and timber are transported along the rivers; — by the Dwina, to Riga; by the Niemen, to Memel and Liebau; and, above all, by the Vistula, to Dantzic and Elbing. Dantzic is the great emporium of Polish grain, of which it usually contains large magazines. There is a large monied interest in Poland, entirely in the hands of the Jews, who have made such large advances to the distressed nobles, that they may be considered the real proprietors of a great part of the lands. They carry on, also, most of the little trade and handicraft which exists throughout Poland.

SECT. VI. *Civil and Social State.*

3135. *The extent and population* of Poland, in 1825, were estimated, in Plater's elaborate Geography of the East of Europe, as follows: they have since somewhat increased: —

		German Square Miles.	Inhabitants.
1. Old Polish Prussia	- -	- 500	800,000
2. Grand Duchy of Posen	- -	- 540	980,000
3. Galicia	- -	- 1500	4,000,000
4. Republic of Cracow	- -	- 20	110,000
5. Kingdom of Poland	- -	- 2270	3,700,000
6. Russian Poland	- -	- 7600	8,800,000
7. Courland	- -	- 450	600,000
		12,980	18,990,000

3136. *The Poles, as already observed, belong to the Slavonic race*, which occupies nearly the whole extent of the vast plains of eastern Europe. They have emerged more than the others from the generally rude and unimproved state which characterises this race; remaining, however, far in arrear of the Teutonic and other western nations. The feudal system, broken up in the greater part of western Europe, exists here in almost undiminished operation. Society consists altogether of two distinct and distant orders, the nobles and the peasantry, without any intermediate degrees. The nobles, who are more numerous than in any other country in Europe, have always, in the eye of the public, formed the people of Poland. They are brave, prompt, frank, hospitable, and gay. They have been called the French of the north, and, both from habits and political connection, are attached to that nation. On the contrary, they regard the Germans with mingled contempt and aversion, calling them *Niemic*, or dumb, in contrast with their own fluency and loquacity. Before their fall, their neighbours called them "the proud Poles." They consider it the deepest disgrace to practise any profession, even law or medicine; and, in case of utmost necessity, even prefer the plough. The luxury of modern times, and the variations in the price of grain, have very generally involved them in pecuniary embarrassments, and placed many of their fortunes in the hands of Jews. The Jews, sober, industrious, parsimonious, crafty, form a numerous and separate people in the heart of Poland. Once a year occur what are called the Polish contracts, when the nobles repair to the principal towns, Kiev, Minsk, Warsaw, Wilna, Novogrodek, &c. to sell their lands, pay their interest, and negotiate all their money transactions. Hither their

wives and daughters resort for amusement; speculators bring their wares; usurers, musicians, strolling-players, sharpers, courtesans, come to ply their respective trades. The Poles, in personal appearance, are handsome and vigorous, though subject to that loathsome and sometimes dangerous disorder called the *plica polonica*. The Polish ladies are celebrated for their beauty, and are considered also more intelligent and agreeable than those of Russia. The peasantry are not absolute slaves, but they are raised little above that degrading condition; an estate being usually estimated by the number of its peasants.

3137. *The religion of Poland*, contrary to that which prevails in the great body of the Slavonic nations, is Roman catholic. This is, perhaps, one main cause of higher civilisation; for the catholic religion, though, in comparison with the protestant, it be unfavourable to intelligence and improvement, has an opposite character when compared with that of the Greek church. Preaching has always formed an essential part of its worship, which gives it a decided superiority over a system which excludes that mode of instruction, and deals merely in a round of childish ceremonies. There is a considerable number of Greek Christians on the eastern and southern frontiers of Poland; and the numerous body of the Jews, of course, profess their national faith.

3138. *Knowledge has made greater progress in Poland* than in any other of the Slavonic nations. In the brilliant eras of Casimir and Sobieski, she produced men eminent in science; among whom we distinguish Copernicus, the discoverer of the true system of the world. Hosius, advanced to the dignity of president of the Council of Trent, enjoyed, in his own day, a high reputation. Strangers to the language of the more enlightened western nations, the Poles have acquired the talent of speaking and writing Latin with peculiar facility. Nowhere has national history been more diligently cultivated. Every great family keeps a chronicle, in which it records the public and private incidents that have come under its observation, and bequeaths them as a legacy to future generations. A very poetical spirit animates the Poles, and is diffused through all ranks. The peasant sings the beauties of rural nature; while the noble bards celebrate the fortunes and glories of their country. Poland, however, within the last two centuries, has not kept pace with the rapid strides which other nations have taken in science and literature. The authorities of Aristotle and of Albertus Magnus still predominate in its schools of philosophy: its separation from Germany, and its distance from the other literary nations, prevent it from fully imbibing their spirit. Yet the Poles enumerate several living authors, whom they consider as vying with the classic names of the western countries, though their fame has not yet made its way beyond the limits of Poland itself.

3139. *The universities of Poland* have enjoyed considerable reputation: that of Cracow, three centuries ago, was one of the most flourishing in Europe: it not only attracted crowds of native students, but drew others from all the neighbouring kingdoms. The distracted state of the country, with the rising reputation of the German seminaries, gradually thinned their number; and the final blow was struck by its subjection to Austria, which introduced the German language, of all other things the most abhorrent to the Poles. A revival seemed to be promised, by the arrangement which fixed Cracow as an independent republic; but this expectation has not yet been fulfilled. The emperor Alexander founded, in 1821, a university at Warsaw, which he endowed with a revenue of 35,200 Polish florins, supporting an establishment of forty-two professors. It was attended, in 1830, by 589 students. Another, in 1820, had been formed at Wilna, also well endowed and regulated; and containing, in its dependent gymnasia, no less than 433 teachers. The university of Leopold, in Galicia, is entirely German. Amid all these aids, however, knowledge is still far from being widely diffused among the body of the people.

3140. *The fine arts* of architecture, painting, and statuary, can scarcely be said to exist in Poland. Some of the carvings in the middle ages are said to possess a degree of merit; but no modern artist has given lustre to the kingdom. Music, on the contrary, is cultivated with ardour and success; though it is the performers, rather than the composers, of Poland that have attained distinction.

3141. *The amusements and mode of life* among the higher ranks are chiefly copied from the other nations of Europe, particularly the French. The Polish dances, however, are strictly national, and very graceful. That, especially, called the Polonaise is marked by a slow majesty of movement, which has been remarked as worthy of a nation who elected their kings. The Poles have a singular manner of shaving the head, leaving only a tuft of hair on the crown, and mustachios are generally worn.

SECT. VII. *Local Geography.*

3142. *The local description of Poland*, in its present dismembered state, must necessarily be given according to the three portions now held in such wide separation from each other:—1. Prussian Poland, with which we shall combine Ducal Prussia; 2. Austrian Poland,

which has received the name of Galicia ; 3. Russian Poland, including the recently formed kingdom of Poland.

SUBJECT. 1. *Prussian Poland, with Ducal Prussia.*

3143. *The two Prussias* form an extensive range of sea-coast, describing a sort of semicircle of nearly 400 miles round the southern shore of the Baltic, and extending their territories from 50 to 100 miles into the interior. The whole is a continuous and almost dead level, scarcely rising above the surface of the water on which it borders. Only in the south-east quarter appear a few sand-hills, blown together by the winds: one of them rises to 500 feet, but none of the others attain half that elevation. Yet, in the absence of any real mountains, these are called by the natives Berge. A range of such sand-hills, or banks, defends the flat coast from the incursions of the sea. In West Prussia there are a few similar *mountains*, and the river banks are somewhat higher than the rest of the country; while there is a gradual, but insensible, rise from the shore to the interior. The lands near the coast, however, would be scarcely secure from inundation, were not the sea itself so extremely shallow. Prussia has scarcely any important rivers exclusively its own, the Pregel forming almost the only exception; but the Vistula and the Niemen, or Memel, after traversing some of the finest provinces of Poland, enter the sea within its territory, and thus afford ample range both for foreign and interior trade. Two extensive waters, called haffs, the Frische Haff and the Curische Haff, exist in an intermediate state between lakes and bays. They form long canals, separated from the sea by a narrow partition. The water is fresh; and it is only when the waves of the Baltic are impelled into them by high tides or storms, that a saline tincture is communicated.

3144. *Prussian industry* is divided between agriculture and commerce; manufactures being yet in their infancy. The soil is in many places sandy and marshy; yet there are few parts which are not fit either for grain, flax, or hemp, and many tracts are very productive. West Prussia, however, which remained, till 1772, under the Polish régime, is much behind in respect to cultivation, though considerable improvement has taken place since its annexation to Prussia. The cattle are numerous, and the breeds in general good: that of horses, in some parts of East Prussia, is extremely fine. The breeding of cattle, however, seems to have declined remarkably since the disastrous year 1806; the number, which, in 1807, was 228,800, having fallen, in 1812 and 1813, to 151,560. The sheep cannot be compared with the fine breeds of Silesia and Saxony, but a good deal has lately been done to improve them. Hogs are reared in very great numbers; and honey is also a copious article. The woods are very extensive, covering, in East Prussia, upwards of 3,000,000, and in West Prussia more than 2,000,000 acres; and their products, timber, pitch, tar, ashes, form an important branch of national wealth. Amidst the generally low state of manufactures, that of coarse woollens, for domestic use, is extensively carried on; flax is well spun, and exported in the shape of yarn; and the tanning of leather flourishes. The commerce of Prussia is extensive; her ports and rivers affording the chief outlet for the copious productions of the soil of Poland. Memel, Königsberg, Elbing, and, above all, Dantzic, rank with the most flourishing commercial places in Europe. The chief staple of export is grain, in large quantities, and of the finest quality; wood, potashes, linen yarn, leather, hemp; in return for which, they receive the fine manufactures, wine, colonial produce, and all the luxuries of life.

3145. *The population of East Prussia* is stated by Jacob to have amounted, in 1827, to 1,171,000; that of West Prussia to 752,000. The former country has a character almost entirely German: the religion is Lutheran, with only about a sixth of Catholics, and a very few Jews. The means of knowledge and instruction are very widely diffused, and accessible to all ranks. In West Prussia, on the contrary, the two religions are nearly equally divided, most of the Polish population being catholic; there are upwards of 12,000 Jews, and the same number of Anabaptists.

3146. *Königsberg*, the capital of East Prussia, and formerly of the Prussian monarchy, is advantageously situated on the Pregel, not far from its junction with the Frische Haff. It is divided into three principal parts, the old city, the Lobenicht, and the island of Kneifhof, where a considerable number of the houses are built on piles, as in Venice and Amsterdam. The walls are nine miles in circuit: a great proportion of the space enclosed by them, however, consists of open ground; but they no longer render Königsberg a strong place, and the citadel of Fredericksburg, in the island, is now covered with shops. Beyond the walls are four suburbs. The university is well endowed, and attended by 200 or 250 students. All the manufactures that exist in the country are concentrated at Königsberg; and they are various, though none of them extensive. Königsberg was an eminent Hanse town, and still carries on a very extensive trade. In 1816 were laden here 634 ships, of which 491 took 23,000 lasts of grain. Kant, the celebrated metaphysician, was a native of this city.

3147. *Of the other towns of East Prussia*, one of the most considerable is Memel, strongly fortified, and which, notwithstanding its smaller size, carries on nearly as great a

trade. In 1828, 869 vessels entered, and nearly the same number cleared out. Of the ships entering inwards in 1828, no fewer than 428 were British. Pillau, on a channel somewhat more than half a mile broad, serves as a sort of subsidiary haven to Königsberg. In 1820 it received 623 vessels, of 43,675 tons burthen, and sent out 638 of 46,292 tons burthen. Braunsburg, near the mouth of the Passarge, exports a large quantity of linen yarn, with masts and corn. Tilsit, on the Niemen, is rather a handsome and considerable town, with some manufactures; but is chiefly remarkable for the treaty of 1807, between Napoleon and Alexander. Gumbinnen and Insterburg, both on the Pregel, are considerable towns. Friedland and Preuss-Eylau deserve mention, chiefly for the great battles fought there in the campaigns of 1806 and 1807.

3148. *Dantzic*, the grand emporium of Poland, stands undoubtedly foremost among the towns of Western Prussia. It lies on the western branch of the Vistula, immediately before its entrance into the sea, at the point where it receives two small tributaries, the Radau and the Mollen. Dantzic is divided into a number of parts, of which the principal are the old city, ill built, wholly in the style of the middle ages, with narrow, gloomy, angular streets; the "high city," as it is called, more modern, and better built, but still far from handsome; the "low city," divided into the Long Garden, which contains the best and most agreeable houses, and the Magazine Island, containing, as its name imports, the chief warehouses of the merchants. The suburbs were, till lately, extensive, one of them being named Old Scotland, from a colony of that nation established at an early period. These suburbs were burned, however, in the sieges by the French, in 1807, and the Russians, in 1813; and, though partly rebuilt, their population has been reduced from 7860 to 1788. The only handsome building is the Lutheran church, with a celebrated picture of the Last Judgment. The commerce of Dantzic is very great. In 1828, 1050 ships entered the port, of the burthen of 101,234 tons; of which, 211 ships, carrying 30,095 tons, were from England. During the last three or four years, this commerce has increased still further. As already observed, the exports of wheat from Dantzic, in 1830, were 404,000 quarters, of which *three fourths* were for England. Between 1807 and 1814, it is estimated to have suffered a loss of 62,500,000 guilders (5,250,000*l.*). The population, in 1817, was 52,821, including the military; but, independent of them, was 47,934. At present it may amount to 60,000. Dantzic has a public library of 27,000 volumes, and also several literary institutions.

3149. *Other towns in West Prussia* are, Elbing, on the river of its own name, which falls into the Frische Haff. Though not nearly equal to Dantzic in respect of foreign trade, it carries on a very extensive interior traffic; and about 1400 vessels, though of comparatively small size, enter and leave its port. It is a fortress, though not now of much importance. Thorn is a considerable city, about an hundred miles up the Vistula, once very strong, and celebrated as the birthplace of Copernicus. Marienburg and Marienwerder are capitals of circles, and places of some consequence.

3150. *Posen*, bearing the title of grand duchy, is now the principal part of the Polish territory annexed to Prussia. It forms an extensive level plain, analogous in all its features to that which crosses the whole north of Europe. The country is finely watered, having the Vistula for its eastern boundary; while the Wartha, receiving the considerable tributaries of the Netze and the Obra, traverses it from east to west, enters Germany, and falls into the Oder at Kustrin. The canal of Bromberg unites the Vistula with the Netze, and, consequently, gives it a communication with the Oder. Agriculture is in a very backward state, and conducted only according to antiquated processes. The peasantry have been freed from personal slavery, but they are still ignorant, drunken, and poor. Yet Posen yields a considerable surplus of grain, which is transported, partly to Dantzic, by the Vistula, and partly, by the Oder, to Stettin. The produce in cattle and sheep, which was once most extensive, has suffered severely from the repeated ravage of hostile armies; yet a considerable quantity is still furnished to Silesia. Although this cannot be considered a manufacturing district, yet it fabricates a considerable quantity of coarse woollen and linen cloth, which is even sent to Russia and Germany. The inhabitants, who are estimated by Hoffmann at 847,000, are divided, as to religion, into 553,000 Catholics, 238,000 Lutherans, 52,500 Jews, with some minor sects. According to Mr. Jacob, the governments of Posen and Bromberg had risen, in 1827, to 1,045,000. The heads of the catholic church are the archbishop of Gnesna and the bishop of Posen. The establishments for public instruction are yet in their infancy.

3151. *Posen* is a large town, on the Wartha, well and regularly built, with broad streets, and a spacious market-place. Population, 25,000. There are several handsome private houses, both in the city and in a spacious suburb on the opposite side of the river. The chief public buildings are, the Stanislaus church, built in the Italian style; the bishop's palace, and the theatre. The governor, who, under the title of *stadtholder*, represents the king, resides at Posen. The city contains 4000 Jews, and a number of families who report themselves as descended from English and Scotch ancestors. The Catholics have a gymnasium, with 500 scholars.

3152. *The other towns of Posen* are, in general, small. Gnesna, formerly a city of great importance, and the ecclesiastical capital of Poland, does not now contain four thousand inhabitants. Lissa is now a large place, with pretty extensive manufactures, and a population of 7934, half composed of Jews. Bromberg, on the canal which bears its name, enjoys a considerable trade.

SUBSECT. 2. *Austrian Poland.*

3153. *The portion of Poland* annexed to Austria is erected into a kingdom, under the titles of Galicia and Lodomeria. These names are derived from the ancient Russian principalities of Halicz and Wlodomir. Its surface is considerably distinguished from that flat marshy level which covers almost the whole of Poland. A great part of it is situated upon the slope of the Carpathian chain, which separates it from Hungary. This is, indeed, only a border range, all whose loftiest peaks are Hungarian; but branches or spurs from it cover a great part of Galicia, before they descend to the great Polish level. The country is thus of very various character. A considerable part consists of mountain forest, the elevations of which do not, however, rise to more than 4000 or 5000 feet: many of the plains are sandy; but the greater portion, diversified by gentle hills, is of the most exuberant fertility; and, notwithstanding its imperfect cultivation, forms a sort of granary of the surrounding countries.

3154. *The various changes which this southern part of Poland* has undergone have rendered it not so strictly Polish as some of the others. About the twelfth century it formed part of the Russian kingdom of Kiev, and bore in great part the name of Red Russia. When Kiev became Russian, Hungary, once united, but now separated from it, laid claim to the Polish provinces; but it had to contend with the Polish monarchy, then in the zenith of its power, under Boleslaus and his successors. After a struggle of several centuries, Hungary was compelled to cede these districts; though still, by a singular clause, reserving a certain claim to them. Maria Theresa, therefore, when she achieved the partition, could boast of a certain ancient right; and Hungary even claimed the incorporation of these new provinces, and a seat for their nobles in the diet; but the Austrian cabinet, however much disposed to avail themselves of the claim, did not choose to press it to this conclusion. The extent of Austrian Poland has not been materially altered since the final partition in 1792. Austria has given to Galicia a form of states, but without allowing them any voice in the making of laws, or in fixing the amount of taxes, though they have some control over their distribution. The states are composed of four orders; the clergy, the nobles, the knights, and the cities: but the Gallician House of Commons consists merely of two deputies from Lemberg, no other place having yet been raised to the rank of city.

3155. *The different branches of industry* are in a less advanced state in Galicia than in any other part even of Poland. The peasantry are no longer in the legal condition of serfs; but the general poverty, sluggishness, and apathy, which prevail among this order, render them nearly as much as ever enthralled to their landlords, and strangers to every kind of improvement. Still the produce of corn on these fine plains is very considerable, being estimated by Blumenbach at 34,000,000 metzen, a large proportion of which is sent partly by the Vistula to Dantzic, and partly to the neighbouring districts of Hungary and Silesia. Although a great portion of Galicia is peculiarly adapted to pasturage, yet the diligence of the people in rearing cattle, &c. is so slender, that not only the breeds are poor, but their amount does not correspond to the extent of pastures. The number of horses in 1817 was 311,000, which, unless in some studs formed by government, had few properties of the noble Polish breeds; horned cattle 1,116,000, and sheep 480,000; not so many as are found in some of the small Saxon provinces. The woods are of considerable value, and some coarse articles of furniture are made out of them and exported. The hills enclose several thousand little lakes, or ponds, remarkably well stocked with fish. The country is infested with wild animals, which the Austrian government has been at great pains to extirpate. In 1812, premiums were paid on the bodies of 10 bears and 2046 wolves. Manufactures even of the coarsest and most necessary articles are almost unknown to the native Gallician, who follows nothing but his plough and his horse, and leaves the care of clothing him to the Jews, who have multiplied in this kingdom more than in any other part even of Poland. They exceed 200,000, and have 294 synagogues. It is but fair to state that the Austrian influence, however violently and unjustly established, has been employed to introduce a certain improvement in all the above particulars.

3156. *The mineral kingdom* affords one branch of industry in which Galicia excels every other part of Europe, and of the world itself. The whole soil at a certain depth contains a mineral layer variously impregnated with salt. The two grand works are at Bochma and Wieliczka, the former of which produces the finest salt; but the latter are the most extensive of any in Poland, or, indeed, perhaps in the world. They extend 6700 klaftern in length, 1100 in breadth, and reach to a depth of 750. The alleys and passages cut out in the solid salt present a brilliant and magical appearance. Some elegant little chapels, adorned with saints and crucifixes, are also cut out in the mineral; but it is said there is no truth in

the current report that there are habitations for the workmen, though there are stables for the horses employed. Of the different kinds and qualities of salt, the purest is called crystal salt, appearing in the shape of cubes and prisms; another, called green salt, contains a large proportion of earth; while the most inferior kind is fit only for cattle. These two great salt mines produce annually upwards of 800,000 cwt.; besides which there are twenty-six on a smaller scale, yielding about 900,000 cwt.

3157. *The commerce of Galicia* is necessarily inland. Occupying, however, the heads of the Dniester and the Vistula, it sends a considerable quantity of commodities down those rivers. It has also a great inland carrying trade, being the principal channel by which intercourse is maintained between Germany and Prussia. The exports consist of grain, salt, some wood, and honey; in exchange for which are received manufactured goods of every description, and exotic luxuries of every denomination. The quantity of these must be somewhat strictly limited by the means of purchase, and the small number who consume more than the absolute necessities of life; yet the German politicians labour under some dread of an unfavourable balance.

3158. *The social state of Galicia* presents an aspect less altered from the feudal system and habits, than that of almost any other European region. The census of 1818 gave 3,760,000, while in 1829 it is stated by Colonel Traux at 4,385,000. These inhabited ninety-five cities, 191 market towns, and 6009 villages. The nobles amounted in 1817 to the enormous number of 31,006; some of them possessing immense property, even whole provinces; though, in consequence of trusting the management of their affairs to stewards, they are generally embarrassed. But a great proportion are in a state of extreme poverty, and even cultivate their fields with their own hands. The burghers were reported at the singularly small number of 11,513; while the country labourers are supposed to be rated too low at 353,419. The Jews constitute every where the most flourishing part of the citizens. The Christians are divided between the Romish and Greek persuasions: the former have 1066, the latter 2800 cathedrals. There are about 5000 Armenians, and thirty protestant congregations scattered through the kingdom. Knowledge is in a most defective state; and the few institutions which exist for its diffusion have been introduced by the Austrians. They have made great exertions to improve the university at Lemberg, which has twenty-six professors, and a good library. The Gorales, or inhabitants of the mountains, form an entirely different race from the Mazurakes, who occupy the level districts; and an old enmity reigns between these two tribes. The Gorales are a fierce, highland race, constantly armed with the axe, with which they can strike an object at the distance of forty yards; and they brandish this weapon even at their dances and festivals. Till repressed by the vigorous measures of the Austrian government, they were accustomed to make most formidable *raids* upon the low country adjoining. The inhabitants of the eastern part of the kingdom are of Rousniak or Russian origin: they speak a language compounded of the Russian and Polish; they are more industrious than the Poles, and employ themselves in the fabrication of coarse linen. A considerable number of Wallachians, of Magyars, the prevailing people in Hungary, and Germans to the number of 72,000, have found their way into Galicia.

3159. *The cities and towns in this part of Poland* are neither very ample nor elegant. Lemberg, however, called by the Poles Leopold, or the city of Leo, founded in the twelfth century, though its interior streets be narrow and old-fashioned, has four handsome suburbs. In 1808 it contained 41,500 inhabitants; of whom 12,700 were Jews. By the small river Pelleir it communicates with the Bug; but its chief trade is by land with Turkey and Russia. The intercourse with this last country, however, is chiefly carried on by the large but ill-built frontier town of Brody, containing from 16,000 to 20,000 inhabitants, of whom more than a third are Jews. The other towns contain only about 5000 or 6000 inhabitants. Among these may be mentioned Przemyzl, once the seat of a principality; destitute of walls, but still defended by a strong castle, and having in its vicinity large manufactures of wood. Jaroslaw, the city of Prince Czartoryski, has a fine cathedral, and may boast of some industry, the Austrians having introduced a fine cloth manufacture. Zlaczow borders on Russia, amid extensive woods and numerous ponds. Sambor and Drohobitz, on the Dniester, have some manufacture and trade, chiefly carried on by Jews. Tarnopol, farther to the north, is tolerably flourishing. Stanislaus, in the south, is a handsome town, which the Austrians propose to convert into an important fortress. Stry is situated in the heart of the mountain district, amid woods, streams, and torrents. Cultivation is extremely rude; yet the Jews have introduced some slight branches of industry. Halicz, from which Galicia derives its name, is now a small place, chiefly occupied by a particular sect of Jews. Bochnia and Wieliczka, entirely supported by the salt mines, do not contain more than 3000 people.

SUBSECT. 3. *The Kingdom of Poland.*

3160. *The partial revival of the kingdom is an act of Russian policy.* The name of Poland, even after the downfall of the great power which it once designated, and the division of the country among the surrounding potentates, was still grateful to the ear of every genuine

Pole. This disposition was manifested in a manner not to be mistaken, when Napoleon over-ran Poland, and proclaimed its erection again into a kingdom. Although the Poles could not, under his sway, hope for much civil liberty, they rallied round him; and, had not his ambition overleapt itself, by urging him into the frozen and hostile regions of Muscovy, his dominion over Poland might have become stable and permanent. Napoleon fell; and Alexander, in reward of his own achievements in the common cause, grasped the regions of the Vistula, including the capital, which had formerly belonged to Prussia, and had been erected by Napoleon into the Duchy of Warsaw. These, with the country on the Bug and the Narew, he formed into the kingdom of Poland, containing only a small portion of what that country had been in her glory, but yet comprising its most improved districts, and those most decidedly Polish.

3161. *The kingdom of Poland* contains an extent of 2270 German square miles, of fifteen to the degree, belonging generally to the vast Polish level, except its southern border, along the waiwodats of Cracow and Sandomir; along which is an extensive and steep though not lofty branch of the Carpathians. The highest point is called the Sysa Gora. The plain, of which the greater part of the newly erected kingdom consists, is rather of a sandy character, and the overflowing of its large rivers often converts it into marsh. It does not possess the exuberant fertility of the Ukraine, and of other southern provinces, celebrated for that very fine wheat with which the port of Dantzic supplies the rest of Europe. Generally speaking, however, it is a good grain country, and under tolerable cultivation. The manufactures of linen and woollen cloth for domestic consumption are considerable, though they produce none of fine quality. In the capital, the making of carriages and harness is of such extent as to assume almost a national importance. Minerals are not a leading feature, though there are iron mines of some value in the southern range of hills. There is a great transit trade of grain down the Vistula, partly the produce of the kingdom itself, but chiefly of the more fertile regions to the south; but the new Poland labours under a severe disadvantage in not possessing the mouth of that river, and its port of Dantzic, which has been annexed to the Prussian territory.

3162. *A representative constitution*, as already observed, was granted by Alexander, in his quality of king of Poland. The new diet was divided into two chambers, one of which is elected by the nobles and the provincial assemblies, while the senate consists of ten waiwodes appointed by the emperor in his character of king of Poland, ten castellans nominated by the senate, and ten bishops. This constitution, however, granted in a liberal and conciliatory spirit, was not found to work so agreeably as a sovereign elsewhere despotic could have desired. It became the aim of the prince to abridge the privileges which appeared to him to be too liberally used. The diet was less frequently assembled; the liberty of the press, at first granted, has been withdrawn. These encroachments kindled a discontent, which broke out in the late strenuous effort to effect an entire emancipation from Russia, the unfortunate issue of which, it is to be feared, will for the present deprive Poland of many of the advantages she has hitherto enjoyed.

3163. *Warsaw*, capital alike of old and of new Poland, is finely situated on the Vistula. During the war which terminated in the subjugation of Poland, Warsaw stood the heaviest brunt; and its population in 1782 was reduced to 75,000; but since that time it has rapidly improved, and in 1829 it contained 150,000, of which, however, about 14,000 were garrison.

GOVERNMENT PALACE AT WARSAW.

buildings; but the finest part of Warsaw consists of its four suburbs having separate rights and jurisdictions. That of Praga, once a strong citadel, was almost destroyed in the dreadful assault by Suwarrow, in 1795: it is now, however, rebuilding. Warsaw originally consisted almost entirely of wooden houses; but that material is now prohibited; and out of its 4000 houses, 3000 are constructed of stone. During the period of its calamities, Warsaw lost the finest collections made by its former sovereigns. The gallery of paintings formed by king Stanislaus, and the Za-

PALACE OF THE MINISTER OF FINANCE.

louski library, were transported to Petersburg; and another library, of more than 45,000 volumes, was transferred to Volhynia. Alexander, however, in 1821, founded, or rather re-endowed, the university.

3164. *The other towns in the kingdom of Poland* are only of secondary importance. Lublin, which ranks second, contains 10,000 inhabitants. It is situated on the Bug, in one of the most fertile districts of the kingdom, and communicating on the south with others still more fertile. It is distinguished by the castle of Casimir the Great, the palace of Sobieski, some fine churches, and the largest synagogue of Poland. Zamosc, in the same vicinity, is an important fortress, while Pulawy, a seat of Count Czartoryski, and Klemenz, the residence of the Zamoyski, are adorned with some elegant and classic edifices. Kalisz, on the Prosna, is rather a well-built town, with 8000 inhabitants, a military school, and some manufactures. The voivodate of Sandomir contains a city of the same name, with a fortified castle, but only 2700 inhabitants; and Radom, also a small town, ranks as its capital. Kielce, capital of the mining district, in the voivodate of Cracow, has a school of mines, and about 5000 inhabitants.

3165. *The republic of Cracow*, in default of any place more strictly appropriate, may be here introduced. The three great powers who decided on the destinies of Poland, by a species of caprice, established at a central point between them this free and neutral city, an ancient and venerable capital of Poland. The degree of freedom which it enjoys, though only by sufferance, has rendered its environs more fertile and smiling than those of the rest of Poland. Its surface contains 2360 square leagues; and in 1819 the population of the city amounted to 24,800, that of the territory to 71,000; of which 12,000 were Jews. The university, once the great school of the north, and frequented by crowds of students, was broken up during the civil commotions, and the attempts to restore it have been fruitless. It has at present thirty professors, but not more than 276 students. Cracow is decidedly a catholic city, and contains eighty-seven monasteries and 164 nunneries. The revenues of the republic amount to 1,379,000 florins. The cathedral is remarkable for the tomb of St. Stanislaus, the monument of Sobieski, and other venerated mausoleums.

SUBJECT. 4. *Russian Provinces.*

3166. *The Lithuanian provinces* form an extensive portion of Poland, the character of which is materially different from that of the rest. The two states, after being entirely separate, were united, as already mentioned, in the fourteenth century, by the marriage of Jagellon, grand duke of Lithuania, with Hedwig, the heiress of the Polish monarchy. This union, however, produced on Lithuania nearly the effect of a subjugation; the kings fixing their residence at Warsaw, and the diet being oftener held there than at Grodno. They passed with comparatively little reluctance under the Russian yoke, and made no movement to meet the attempts of Napoleon to re-establish Poland. The soil is very generally either sandy or marshy, and buckwheat is the crop principally raised. The pastures are excellent, and the forests fine and very extensive; honey and potashes are staple productions. The forests are infested with numerous wolves, bears, and other wild animals; and specimens of the urus are still found in them. The inhabitants appear to rank lower in industry and civilisation than either the Russians or Poles. Every branch of trade is in the hands of the Jews, who sometimes even buy the corn before it is in the ear. The appearance of the peasantry indicates the most extreme poverty. Many of them are clothed merely in sheepskin, their shoes made of the bark of trees, their carts of mountain ash, joined together without iron. White and Black Russia are names applied to several of the more eastern provinces of this part of Poland. They were, as the name implies, conquered at an early period from Russia, by the dukes of Lithuania. Those provinces present in a more decided manner all the features which characterise Lithuania. The forests and marshes are more extensive, the industry of the people still more relaxed, and the arts in a ruder state. The roads are almost impassable, the villages mean; and in the houses men, women, and cattle, are often lodged under the same roof. The palatinates of Polotsk, Witepsk, Mscislaw, Mohilew, and Minsk, were comprehended in White Russia, while Black Russia was a name applied only to that of Novogrodek.
